

**METHOD OF REGULATING HEMATOPOIETIC CELL SURVIVAL****CROSS-REFERENCE TO RELATED APPLICATIONS**

This application is a continuation of co-pending International Application No. PCT/AU00/01118 filed September 2000, the entire disclosure of which is incorporated herein by reference. This application claims priority to Australian patent application No. PQ 2875, filed on 15 September 1999 and Australian patent application No. PQ 8733, filed on 12 July 2000, the entire disclosure of which is also incorporated herein by reference.

**FIELD OF THE INVENTION**

The present invention relates to a binding motif of a receptor. In particular, the binding motif is a cytoplasmic domain associated with stimulation of receptor mediated activities. The present invention further contemplates methods of using the motif in particular for mediating activities of receptors.

**BACKGROUND OF THE INVENTION**

The action of signalling molecules such as cytokines has been poorly understood. It is apparent that these cellular proteins can switch on activities within cells. However, the actual triggering mechanisms and how these are relayed to culminate in their final activities is not known. Cell cycles are clearly involved but the link between the triggering molecule and receptor and actions such as cell survival, proliferation, and differentiation is unclear.

Proteins including human granulocyte-macrophage colony-stimulating factor (GM-CSF), interleukin-3 (IL-3), and IL-5 are capable of stimulating normal and transformed hematopoietic cells. With each, the initiating event for signal transduction is the binding of the protein to their surface receptors. These receptors may be composed of subunits such as the  $\alpha$  chain and a common  $\beta$  chain ( $\beta_c$ ). Engagement of  $\beta_c$  by the binding of the cytoplasmic protein to surface receptors results in the stimulation of cell survival, proliferation, and differentiation and mature cell effector function in the appropriate lineage, a fact that emphasises the major signaling role played by  $\beta_c$  in mediating receptor induced biological activities.

One of the first events in activation of receptors and in the initiation of the signaling cascade is tyrosine phosphorylation of  $\beta_c$ . This is a common theme among receptor signaling subunits and can be seen in homodimeric receptors  
 5 such as the erythropoietin (EPO) receptor, thrombopoietin (TPO) receptor, and granulocyte colony-stimulating factor (G-CSF) receptor as well as in heterodimeric receptors such as in the IL-6 and IL-2 receptors, and in the GM-CSF, IL-3, and IL-5 receptor systems.

10 Tyrosine phosphorylation of receptor signaling subunits appeared to be a critical step in the creation of docking sites for the association of signaling molecules. Despite the perceived importance of tyrosine phosphorylation of receptors, it is becoming apparent that signaling can proceed in its absence. This is demonstrated in the EPO and TPO receptors, in which the substitution of all  
 15 tyrosines failed to abolish their activities.

It has been unclear until now how the binding of proteins to their receptors can result in the specialised functions associated with these molecules and their receptors. The signaling events which lead to the specialised functions are  
 20 unknown. However various cellular proteins are implicated in the cascade of events culminating in the biological functions associated with various molecules. There are many ubiquitous proteins involved in cell signaling pathways and any one or more may be involved in relaying signals switched on by proteins binding to their receptor.

25

The 14-3-3 family of proteins is one such protein, which consists of 7 different isoforms and is expressed ubiquitously from yeast to humans. The ability of 14-3-3 to bind to a number of motifs in a wide range of signaling molecules suggests that 14-3-3 proteins may participate in a number of cell signaling pathways that  
 30 may include mitogenesis, transformation and survival. Although 14-3-3 has been shown to bind a number of signaling molecules, it has been more difficult to determine how or where 14-3-3 can regulate signaling events directly or indirectly, or whether 14-3-3 is implicated at all.

Accordingly, an object of the present invention is to overcome some of the problems of the prior art and to understand how proteins can express their biological activities and to use this information to manipulate cellular functions.

5

### SUMMARY OF THE INVENTION

10

In one aspect of the present invention, there is provided a binding motif of a receptor capable of binding a cytoplasmic protein, said binding motif comprising an amino acid sequence wherein at least one amino acid is serine/threonine.

15 Preferably, the serine/threonine residue corresponds to a serine residue at position 601 of the common  $\beta_c$  according to Figure 1 (SEQ ID NO:1).

Preferably the binding motif comprises an amino acid sequence including the sequence

20 -S-X-S/T- (SEQ ID NO:2)

wherein the X is any amino acid.

Applicants have found that the second serine/threonine of the motif is an indicator of the cytoplasmic protein binding motif. However, the motif as a whole is  
25 involved in the cytoplasmic binding and requires the serine/threonine residue along with flanking amino acids.

Preferably, the motif includes flanking amino acid sequences which may improve the binding of a cytoplasmic protein to the binding motif. More preferably the  
30 flanking amino acids are selected from R and X-P (wherein X is any amino acid such that the flanking amino acids individually or co-operatively contribute to the binding motif for binding to a cytoplasmic protein.

More preferably the amino acid sequence of the binding motif includes the sequence:

-R-S-X-S/T-X-P- (SEQ ID NO:3)

wherein X is any amino acid.

5

In a preferred aspect of the present invention, there is provided a binding motif of a receptor capable of binding a cytoplasmic protein, said binding motif comprising an amino acid sequence, a functional equivalent or analogue thereof and wherein at least two (2) of the amino acids are serine.

10

The receptor may be any receptor that is capable of binding to an extracellular molecule or protein and which mediates its function through the binding of a cytoplasmic molecule or protein such as 14-3-3 protein, or any cytoplasmic molecule or protein capable of binding a further signaling molecule which activates a cascade of events leading to cell signaling pathways and biological functions such as mitogenesis, proliferation, transformation, differentiation and cell survival, or any other cytoplasmic molecule or protein which does not signal. This molecule may act as an antagonist. More preferably, the cytoplasmic protein is 14-3-3.

20

Preferably the receptor is selected from the group including:

- (1) GM-CSF/IL-3/IL-5 receptor
- (2) IL6 human interleukin-6 receptor beta chain precursor (IL-6R-beta)
- 25 (3) LEPR human leptin receptor precursor (LEP-R) (OB RECEPTOR) (OB-R).
- (4) TNFR2 human tumor necrosis factor receptor 2 precursor (tumor necrosis factor
- (5) VGR1 human vascular endothelial growth factor receptor 1 precursor
- (6) TRK3 human receptor protein-tyrosine kinase TKT precursor (EC
- 30 2.7.1.112)
- (7) Q01974 protein-tyrosine kinase transmembrane receptor ROR2 precursor
- (8) FGR1 human basic fibroblast growth factor receptor 1 precursor (BFGF-R)
- (9) Q15426 protein-tyrosine phosphatase, receptor-type, H precursor (EC
- 3.1.3.48)

**Substitute Specification**

- (10) PTPM human protein-tyrosine phosphatase mu precursor (EC 3.1.3.48) (R-PTP-MU).
- (11) PGDS human alpha platelet-derived growth factor receptor precursor (EC 2.7.1.112)
- 5 (12) FGR4 human fibroblast growth factor receptor 4 precursor (FGFR-4) (EC 2.7.1.112)
- (13) FGR2 human fibroblast growth factor receptor 2 precursor (FGFR-2) (EC 2.7.1.112)
- (14) Q13635 patched protein homolog (PTC)
- 10 (15) MANR human macrophage mannose receptor precursor.
- (16) LRP2 human low-density lipoprotein receptor-related protein 2 precursor (megalin)
- (17) IDD human integral membrane protein dgcr2/idd precursor (KIAA0163)
- (18) AMFR human autocrine motility factor receptor precursor (AMF receptor)
- 15 (19) ACH5 human neuronal acetylcholine receptor protein, alpha-5 chain precursor.
- (20) KKIT human: stem cell growth factor receptor (proto-oncogene tyrosine-protein kinase kit) (C-KIT) (CD117 antigen)
- 20 (21) TPOR human: thrombopoietin receptor precursor (TPO-R) (myeloproliferative leukemia protein (C-MPL). (TPOR or MPL).
- (22) TPOR mouse: thrombopoietin receptor precursor (TPO-R) (myeloproliferative leukemia protein) (C-MPL). (TPOR or MPL).
  
- 25 Preferably, the binding motif of the receptor is capable of interacting with a cytoplasmic molecule or protein such as 14-3-3 protein, or any cytoplasmic molecule or protein capable of binding a further signaling molecule which activates a cascade of events leading to cell signaling pathways and biological functions such as mitogenesis, proliferation, transformation, differentiation and
- 30 cell survival, or any other cytoplasmic molecule or protein which does not signal. This molecule may act as an antagonist. More preferably, the cytoplasmic protein is 14-3-3.

Preferably the binding motif of a receptor has an amino acid sequence selected from the group including:

- |    |         |                        |
|----|---------|------------------------|
|    | (i)     | HSRSLP (SEQ ID NO:4)   |
|    | (ii)    | SSSRP (SEQ ID NO:5)    |
| 5  | (iii)   | SNSKP (SEQ ID NO:6)    |
|    | (iv)    | SDSSP (SEQ ID NO:7)    |
|    | (v)     | SISAP (SEQ ID NO:8)    |
|    | (vi)    | SLSLP (SEQ ID NO:9)    |
|    | (vii)   | SASTP (SEQ ID NO:10)   |
| 10 | (viii)  | SPSFP (SEQ ID NO:11)   |

|    | (xxvii) | KSSESTP (SEQ ID NO:30) |

30 or a functional equivalent or analogue thereof.

In another aspect of the present invention there is provide a phosphorylated binding motif of a receptor capable of binding a cytoplasmic protein, said binding

motif comprising an amino acid sequence wherein at least one amino acid is serine.

Preferably, the serine residue corresponds to a serine residue at position 601 of the common  $\beta_c$  according to Figure 1 (SEQ ID NO:1).

In a preferred aspect of the present invention, there is provided a phosphorylated binding motif of a receptor capable of binding a cytoplasmic protein, said binding motif comprising an amino acid sequence, a functional equivalent or analogue thereof and wherein at least two (2) of the amino acids are serine and wherein at least one serine residue of the motif is phosphorylated.

In a further preferred aspect, there is provided a phosphorylated binding motif of a GM-CSF/IL-3/IL-5 receptor capable of binding a cytoplasmic protein, said binding motif comprising an amino acid sequence of at least <sup>598</sup>HSRSLP<sup>603</sup> (SEQ ID NO:31) of the GM-CSF/IL-3/IL-5 receptor or a functional equivalent or analogue thereof wherein at least Ser<sup>601</sup> is phosphorylated.

In a further preferred aspect, there is provided a binding motif of a GM-CSF/IL-3/IL-5 receptor capable of binding a cytoplasmic protein, said binding motif comprising an amino acid sequence of at least <sup>598</sup>HSRSLP<sup>603</sup> (SEQ ID NO:31) of the GM-CSF/IL-3/IL-5 receptor or a functional equivalent or analogue thereof wherein at least Ser<sup>601</sup> is phosphorylated.

In another aspect of the present invention, there is provided a method of binding a cytoplasmic protein to a receptor, said method comprising:

phosphorylating a binding motif of a receptor as described above, a functional equivalent or analogue thereof; and

30

subjecting the binding motif of the receptor to a cytoplasmic protein.

In another aspect of the present invention, there is provided a method of phosphorylating a binding motif of a receptor capable of binding a cytoplasmic

protein, said binding motif comprising an amino acid sequence of, a functional equivalent or analogue thereof and wherein at least one amino acid is serine, said method comprising binding a triggering molecule to the receptor.

- 5 Preferably, the serine residue corresponds to a serine residue at position 601 of the common  $\beta_c$  according to Figure 1 (SEQ ID NO:1).

In another aspect of the present invention, there is provided a method of phosphorylating a binding motif of a receptor capable of binding a cytoplasmic  
10 protein, said binding motif comprising an amino acid sequence, a functional equivalent or analogue thereof and wherein at least two (2) amino acids are serine, said method comprising binding a triggering molecule to the receptor.

In another aspect of the present invention, there is provided a method of  
15 activating cellular activities said method including:

regulating the activation of phosphorylation of a binding motif of a receptor as described above, a functional equivalent or analogue thereof; and

20 subjecting the binding motif to a cytoplasmic protein, wherein said cytoplasmic protein is associated with activation of cellular activities.

In yet another aspect of the present invention there is provided a method of regulating cellular activities, said method including:

25

regulating the activation of phosphorylation of a binding motif of a receptor as described above, a functional equivalent or analogue thereof; and

subjecting the binding motif to a cytoplasmic protein to bind the cytoplasmic protein to the binding motif; and

30 activating a cell signaling pathway by interacting the bound cytoplasmic protein with a signaling molecule involved in the pathway.

## IN THE FIGURES

Figure 1 shows the amino acid sequence of the common  $\beta$  chain ( $\beta_c$ ) (SEQ ID NO:1).

Figure 2 shows the amino acid sequence of the Stem Cell Growth Factor Receptor (Proto-Oncogene Tyrosine- Protein Kinase Kit) (C-KIT) (CD 117 Antigen) (SEQ ID NO:32).

Figure 3 shows the amino acid sequence of the Human Thrombopoietin Receptor Precursor (TPO-R) (Myeloproliferative Leukaemia Protein) (C-MPL) (SEQ ID NO:33).

Figure 4 shows the amino acid sequence of the Mouse Thrombopoietin Receptor Precursor (TPO-R). (Myeloproliferative Leukaemia Protein) (C-MPL) (SEQ ID NO:34).

Figure 5 shows that Human  $\beta_c$  associates with 14-3-3 $\zeta$  and this association is mediated by the 544-626 region of  $\beta_c$ . HEK 293T cells were either mock transfected (mock), transfected with wild type  $\beta_c$  (wt) or  $\beta_c$  containing C terminal deletions. Lysates were prepared from transfected cells and either immunoprecipitated with anti-14-3-3 $\zeta$  antibody (A) or precipitated with either 14-3-3-GST sepharose (B) or GST-sepharose (C). All proteins were separated on 7.5% SDS-PAGE under reducing conditions before Western blotting with anti- $\beta_c$  antibody (MAb 1C1).

Figure 6 shows that 14-3-3 $\zeta$  specifically binds the HSRSLP motif of the  $\beta_c$  cytoplasmic domain. (A) HEK 293 cells were used either untransfected (UT), or transfected with wild type  $\beta_c$  (wt), or with  $\beta_c$  containing the sequence <sup>581</sup>PHSRSLP<sup>587</sup> (SEQ ID NO:35) mutated to <sup>581</sup>GEFAAAA<sup>587</sup> (SEQ ID NO:36) or with  $\beta_c$  containing the sequence <sup>820</sup>RSKPSSP<sup>826</sup> (SEQ ID NO:37) mutated to <sup>820</sup>EFAAAAA<sup>826</sup> (SEQ ID NO:38). Lysates were made and immunoprecipitations were performed using GST-14-3-3-sepharose. The presence of  $\beta_c$  was determined by Western blotting with an anti- $\beta_c$  antibody (MAb 1C1). (B) The

level of expression  $\beta_c$  in the lysates was determined by Western blotting with an anti- $\beta_c$  antibody (MAb 1C1).

Figure 7 shows that Inhibition of  $\beta_c$  association with 14-3-3 $\zeta$  by phosphorylated but not by unphosphorylated  $\beta_c$  and raf-1 peptides. Lysates of HEK293T cells transfected with  $\beta_c$  were immunoprecipitated with GST-14-3-3-sepharose in the absence or in the presence of chemically-synthesised peptides (100uM) containing a  $\beta_c$  sequence (CLGPPHSRSLPDILG; SEQ ID NO:39) or a Raf-1 sequence (CLSQRQRSTSTPNVHM; SEQ ID NO:40). In the phosphorylated peptides the relevant phosphorylated serine is underlined. The experiment was performed on 7.5% SDS-PAGE under reducing conditions. The presence of  $\beta_c$  in the precipitation experiment was determined by Western blotting with anti- $\beta_c$  antibody (MAb 1C1).

Figure 8 shows that Specific inhibition of  $\beta_c$  association with 14-3-3 $\zeta$  by a phosphorylated peptide encompassing the 579-592 region of  $\beta_c$ . Lysates of HEK293T cells transfected with  $\beta_c$  were precipitated with GST-14-3-3-sepharose in the absence or in the presence of various concentrations of chemically-synthesised peptides. Two  $\beta_c$  peptide sequences were used, CLGPPHSRSLPDILG (SEQ ID NO:39) either non phosphorylated (A) or serine<sup>601</sup> phosphorylated (B), and CPLSLRSKPSPGPGP (SEQ ID NO:41) either non phosphorylated (C) or serine phosphorylated (D). The appropriate phosphorylated serine in each peptide is underlined. The experiment was performed on 7.5% SDS-PAGE under reducing conditions. The presence of  $\beta_c$  in the immunoprecipitates was determined by Western blotting with anti- $\beta_c$  antibody (MAb 1C1).

Figure 9 shows that Binding of <sup>125</sup>I-labeled 14-3-3z to synthetic peptides corresponding to the 14-3-3 binding region of  $\beta_c$ . Microtiter wells were coated with synthetic peptides CLGPPHSRSLPDILG (SEQ ID NO:39) either non phosphorylated or phosphorylated on the second serine (underlined). Various concentrations of <sup>125</sup>I-labeled recombinant 14-3-3z protein were added to

microtiter wells and incubated at 22°C for 2 h. [Insert: Scatchard analyses of 14-3-3 interaction with the serine-phosphorylated peptide].

Figure 10 shows that <sup>601</sup>Ser in  $\beta_c$  is phosphorylated *in vivo* by GM-CSF. (A) The anti-phospho- <sup>601</sup>Ser $\beta_c$  antibody specifically recognises the phosphorylated CLGPPHSRSLPDILG peptide (SEQ ID NO:39). Dot blots were prepared on nitrocellulose filters of either the non phosphorylated or the serine phosphorylated CLGPPHSRSLPDILG peptide (SEQ ID NO:39) and the scrambled peptide CLPLSGPD SHIRGPL (SEQ ID NO:42) before probing with anti-phospho- <sup>601</sup>Ser $\beta_c$  antibody. (B) The serine phosphorylated CLGPPHSRSLPDILG peptide (SEQ ID NO:39) specifically inhibits the binding of anti-phospho- <sup>601</sup>Ser $\beta_c$  antibody to  $\beta_c$ . Lysates of HEK293T cells transfected with wild type  $\beta_c$  were immunoprecipitated with anti- $\beta_c$  antibody (MAb 8E4). Immunoprecipitates were run on 7.5% SDS-PAGE under reducing conditions. Anti-phospho- <sup>601</sup>Ser $\beta_c$  antibody was then pre-incubated with either medium (none), 100 fold molar excess of the serine phosphorylated (1) or non phosphorylated (2) CLGPPHSRSLPDILG peptide (SEQ ID NO:39), or the scrambled peptide CLPLSGPD SHIRGPL (SEQ ID NO:42) (3). The filters were then Western blotted and probed with the pretreated anti-phospho- <sup>601</sup>Ser $\beta_c$  antibody. (C) Upregulation of <sup>601</sup>Ser phosphorylation by GM-CSF. M1 cells expressing GM-CSFRa and  $\beta_c$  were either untreated (-) or stimulated with GM-CSF (2ng/ml) for 30 seconds (+). Lysates of the M1 cells were immunoprecipitated with anti- $\beta_c$  antibody (MAb 8E4) and the immunoprecipitates run on 10% SDS-PAGE under reducing conditions. The filters were then Western blotted with either anti-phospho- <sup>601</sup>Ser $\beta_c$  antibody or the anti- $\beta_c$  antibody (MAb 1C1).

Figure 11 shows Phosphorylation of Ser601 of  $\beta_c$  in response to IL-3 and the recruitment of 14-3-3. CTL-EN cells expressing IL-3Ra and either wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were washed, starved for 4 hours in DMEM containing 0.1% FCS and then stimulated with 50ng/ml IL-3 for the indicated times. Cells were then lysed and the  $\beta_c$  immunoprecipitated (7x10<sup>7</sup> cells/IP) with the 1C1 anti- $\beta_c$  specific mAb. Immunoprecipitates were divided and 80% or 20% were separately run on SDS-PAGE and transferred to nitrocellulose

**Substitute Specification**

filters. (a) 80% of the immunoprecipitates were probed with the anti-phospho-Ser601 $\beta_c$  antibody, the filters stripped, and re-probed with the 1C1 anti- $\beta_c$  mAb. 20% of the immunoprecipitates were probed with the 4G10 anti-phosphotyrosine antibody. (b) Regulation of 14-3-3 association with  $\beta_c$  following IL-3 stimulation.

5 CTL-EN cells were starved and stimulated as above, and  $\beta_c$  was immunoprecipitated with the 1C1 mAb coupled to Sepharose beads. Immunoprecipitates were boiled in a non-reducing sample buffer and subjected to SDS-PAGE on a non-reducing gel. Immunoblot analysis was performed with anti-14-3-3 antibodies and the filter stripped and re-probed with the 1C1 antibody.

10 These results were typical of 3 experiments.

Figure 12 shows PKA phosphorylates Ser601 of  $\beta_c$ . a) The ability of either PKA or CKII to phosphorylate purified his $\beta_c$ 445-881 was examined in an *in vitro* kinase assay using  $\gamma$ -<sup>32</sup>PATP. Peptide competitions were also performed using 200mM

15 peptides containing the indicated sequences. b) The ability of PKA and CKII to phosphorylate Ser601 of his $\beta_c$ 445-881 was examined by immunoblot analysis using the anti-phospho-Ser601 $\beta_c$  antibodies. Filters were probed firstly with anti-phospho-Ser601 $\beta_c$  antibodies (top panel). Filters were then stripped and re-probed with an antibody that recognizes the HSRSLP (SEQ ID NO:4) motif of  $\beta_c$

20 regardless of whether Ser601 is phosphorylated or not (anti-HSRSLP $\beta_c$ )(bottom panel). c) To determine if agents that elevate intracellular cAMP and activate PKA also resulted in increased phosphorylation of  $\beta_c$ Ser601, cells were starved for 12 hours and left unstimulated (nil), or stimulated with IL-3 (50ng/ml), forskolin (50mM) or dibutyryl cAMP (100mM) for 10 minutes at 37°C. Cells were then

25 lysed and  $\beta_c$  immunoprecipitated with 1C1. Ser601 phosphorylation of  $\beta_c$  was determined using the anti-phospho-Ser601 antibodies (top panel). The filter was then stripped and re-probed with anti  $\beta_c$  1C1 antibodies.

Figure 13 shows 14-3-3 binding to  $\beta_c$  in response to IL-3 stimulation is required

30 for the recruitment and activation of PI 3-kinase. (a) analysis of PI 3-kinase activity. CTL-EN cells expressing IL-3Ra and either wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were starved for 12 hours in DMEM containing 0.5% FCS and stimulated with 50ng/ml IL-3 for the indicated times. Cells were

then lysed and phospho-tyrosine containing proteins were immunoprecipitated (2x10<sup>7</sup> cells/IP) using the 4G10 antibody. Immunoprecipitates were washed in 1x PI 3-kinase buffer (20mM HEPES, pH 7.5, 5mM MgCl<sub>2</sub>, 1mM EGTA) and PI 3-kinase activity was analysed in a lipid kinase assay using phosphatidyl inositol and g<sup>32</sup>PATP as substrates as described in the "Materials and Methods".

5 Autoradiogram of TLC plate is shown with <sup>32</sup>P-labelled phosphatidyl inositols (PIP) and the origin indicated. These results were typical of 3 experiments. (b) CTL-EN cells were also examined for the association of  $\beta_c$  with p85. CTL-EN cells expressing either wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were starved for 12 hours in DMEM containing 0.5% FCS and then

10 stimulated with 50ng/ml IL-3 for the indicated times. Cells were then lysed and the  $\beta_c$  immunoprecipitated (2x10<sup>7</sup> cells/IP) with the 1C1 anti- $\beta_c$  specific mAb. Immunoprecipitates were then subjected to SDS-PAGE, transferred to nitrocellulose and immunoblotted with anti-p85 (1mg/ml) followed by detection

15 with HRP-conjugated anti-rabbit IgG antibody and ECL. The filters were then stripped, probed with anti-SHP2 (1mg/ml), stripped again and finally probed with 1C1 anti- $\beta_c$  (2mg/ml). These results were typical of 2 experiments. The association of his $\beta_c$ 445-881 with p85 was also assessed in pull-down experiments together with peptide competition. (c) List of peptides used in the his $\beta_c$ 445-881

20 pull-down experiment. S refers to a phospho-serine residue. (d) Association of p85 with recombinant his $\beta_c$ 445-881. his $\beta_c$ 445-881 (10mg) coupled to Sepharose resin and phosphorylated on Ser601 with PKA (lanes 1-5) or Sepharose alone (lane 6) was incubated with COS-7 pre-cleared lysates in the absence (lane 1) or in the presence of 200mM competing peptides (lane 2, scrambled. Lane 3,

25 Ser601Ala. Lane 4, non-phospho-Ser601. lane 5, phospho-Ser601) for 1 hour at 4°C. The resin was then washed extensively, subjected to SDS-PAGE and transferred to a nitrocellulose filter. The filter was immunoblotted with anti-p85 antibodies (1mg/ml) followed by detection with HRP-conjugated anti-rabbit IgG antibody and ECL. These results were typical of 2 experiments.

30

Figure 14 shows 14-3-3 binding to  $\beta_c$  is required for Akt activation but not STAT5, ERK or JNK activation. (a) CTL-EN cells expressing IL-3Ra and either wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were starved for 12 hours

#### Substitute Specification

in DMEM containing 0.5% FCS and then stimulated with 50ng/ml IL-3 for the indicated times. Cells were lysed, whole cell lysates were subjected to SDS-PAGE and transferred to a nitrocellulose filter. Filters were immunoblotted and stripped sequentially with anti-phospho Akt pAb (1:500) anti-phosphorylated  
 5 STAT5 mAb (2mg/ml), anti-active MAPK pAb (50ng/ml) and anti-ERK pAb (1mg/ml) followed by detection with HRP-conjugated anti-rabbit or anti-mouse IgG antibody and ECL. (b) CTL-EN cells expressing IL-3Ra and either wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were starved for 12 hours in DMEM containing 0.5% FCS and stimulated with 50ng/ml IL-3 for the indicated  
 10 times. Cells were lysed and JNK was immunoprecipitated. The immunoprecipitates were then washed in 1x JNK buffer (10mM MgCl<sub>2</sub>, 10mM Tris-HCl pH 7.4) and the JNK activity was then analysed in an *in vitro* kinase assay using g<sup>32</sup>PATP and 1mg GST-jun1-79. Kinase assays were subjected to SDS-PAGE and transferred to a nitrocellulose filter. An autoradiogram of the  
 15 filters is shown.

Figure 15 shows 14-3-3 binding to  $\beta_c$  in response to IL-3 regulates cellular viability. (a) CTL-EN cells expressing IL-3Ra and either wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were washed and then plated in duplicate at  
 20  $2.5 \times 10^5$  cells/ml in DMEM containing 0.1% FCS and either 10ng/ml IL-3, 10 ng/ml IL-2 or 10ng/ml IL-3 and 5 mM LY294002. Viable cells were counted using the trypan blue exclusion method after 4 days. The results shown are typical of 3 experiments. (b) CTL-EN cells expressing IL-3Ra and either wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were washed and then plated in  
 25 triplicate at  $5 \times 10^5$  cells/ml in DMEM containing 0.1% FCS and either no IL-3, 1ng/ml IL-3 or 10ng/ml IL-3. Metabolic activity was measured each day using the CellTiter96 AQueous one solution cell proliferation assay according to the manufacturers instructions. Shown are the raw absorbance values (490nm) plotted against day for CTL-EN cells expressing wt $\beta_c$  in the presence of no IL-3  
 30 (u), 1ng/ml IL-3 (l) or 10ng/ml IL3 (n) and CTL-EN cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant in the presence of no IL-3 (u) or 10 ng/ml IL-3 (i). These results are typical to 2 experiments.

Figure 16 shows 14-3-3 binding to  $\beta_c$  is not required for cell cycle progression. a) CTL-EN cells expressing IL-3Ra and either wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were washed and then plated at  $2.5 \times 10^5$  cells/ml in DMEM containing 0.1% FCS and starved for 24 hours. Cells were then stimulated for a further 24 hours with 50 ng/ml IL-3 in the same medium after which the cells were harvested by centrifugation, fixed in ethanol and stained with propidium iodide. Cell cycle distribution was then analysed by flow cytometry. b) c-myc induction in response to IL-3 stimulation. CTL-EN cells were washed, starved and stimulated with IL-3 for 2 hours as described above. Total RNA was extracted and subjected to Northern blot analysis. Filters were probed sequentially with  $^{32}\text{P}$ -labelled cDNAs for c-myc and 18SrRNA. Signals were detected by autoradiography.

Figure 17 shows 14-3-3 binding to  $\beta_c$  in response to IL-3 stimulation promotes cellular survival by suppressing apoptosis. CTL-EN cells expressing IL-3Ra and either wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were washed and then plated at  $5 \times 10^5$  cells/ml in DMEM containing 0.1% FCS and either 10ng/ml IL-3 or 10 ng/ml IL-2 for 18 hours. Cells were then harvested by centrifugation and stained with annexin V according to the manufacturers instructions. Annexin V positive cells were then analysed by flow cytometry.

Figure 18 shows a proposed model for the regulation of survival by IL-3. Binding of IL-3 to the IL-3 receptor, composed of an  $\alpha$ -chain ( $\alpha$ ) and a  $\beta$ -Chain ( $\beta_c$ ), results in receptor oligomerization (only one  $\alpha$ -chain and one  $\beta$ -chain are shown for simplicity), increased tyrosine phosphorylation and also increased Ser601 phosphorylation (S). Ser601 phosphorylation of  $\beta_c$  allows recruitment of 14-3-3, which in turn recruits PI 3-kinase (PI 3-K) either directly, or indirectly through an additional adaptor molecule. The recruitment of PI 3-kinase and the production of phosphatidyl inositols (PIP) couples the activated receptor to down-stream signalling molecules such as Akt and promotes cellular survival.

Figure 19 shows <sup>601</sup>Ser in  $\beta_c$  of acute myeloid leukaemia (AML) is constitutively phosphorylated. CTL-EN cells expressing IL-3R $\alpha$  and  $\beta_c$  were either untreated or

stimulated with IL-3 (2ng/ml) for 1 or 5 minutes. AML cells expressing GM-CSFR $\alpha$  and  $\beta_c$  were either untreated or stimulated with GM-CSF (2ng/ml) for 5 minutes. Lysates of either CTL-EN cells or AML cells were immunoprecipitated with anti- $\beta_c$  antibody (MAb 8E4) and the immunoprecipitates run on 10% SDS-PAGE under reducing conditions. The filters were then western blotted with either anti-phospho- <sup>585</sup>Ser $\beta_c$  antibody (A) or the anti- $\beta_c$  antibody (MAb 1C1) (B).

Figure 20 shows phosphorylation of Ser601 of  $\beta_c$  in response to IL-3 and the recruitment of 14-3-3.

10

Figure 21 shows PKA phosphorylates Ser601 of  $\beta_c$ . (A) The ability of either PKA or CKII to phosphorylate purified His $\beta_{c445-881}$  was examined in an *in vitro* kinase assay using  $\gamma^{32}\text{P}$ -ATP. (B) The ability of PKA and CKII to phosphorylate Ser601 of His $\beta_{c445-881}$  was examined by immunoblot analysis using the anti-phospho- Ser601 $\beta_c$  antibody. (C) Determination of the  $K_m$  and the  $V_{max}$  for PKA phosphorylation of the  $\beta_c$  peptide. (D) Pharmacologic regulation of PKA activity and its effect on  $\beta_c$ Ser601 phosphorylation.

Figure 22 shows 14-3-3 binding to  $\beta_c$  in response to IL-3 stimulation is required for the recruitment and activation of PI 3-kinase. (A) Analysis of PI 3-kinase activity. (B) CTL-EN cells were also examined for the association of  $\beta_c$  with p85. (C) The association of recombinant His $\beta_{c445-881}$  with p85 and 14-3-3.

Figure 23 shows 14-3-3 binding to  $\beta_c$  is required for Akt activation but not STAT5, ERK, JNK or JAK2 activation. (A) Phosphorylation of Akt, STAT5 and ERK2. (B) Activation of JNK activity. (C) Tyrosine phosphorylation of JAK2.

Figure 24 shows 14-3-3 binding to  $\beta_c$  in response to IL-3 stimulation promotes cellular survival by suppressing apoptosis. (A) Cellular viability. Shown is the viability of CTL-EN cells expressing wt $\beta_c$  in the presence of IL-2 (●) or IL-3 (■) and the viability of CTL-EN cells expressing  $\beta_{c\text{HSRSLP}}$  (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) in the presence of IL-2 (▼) or IL-3 (▲). Shown are the raw absorbance values (490nm) plotted against day for CTL-EN

cells expressing wt $\beta_c$  in the presence of no IL-3 ( $\blacktriangledown$ ), or 10ng/ml IL-3 ( $\blacksquare$ ), and CTL-EN cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4) $\rightarrow$ EFAAAA (SEQ ID NO:43) mutant in the presence of no IL-3 ( $\blacklozenge$ ), or 10 ng/ml IL-3 ( $\blacktriangle$ ). (C) DNA laddering. (D) Annexin V and propidium iodide staining.

5

Figure 25 shows 14-3-3 binding to  $\beta_c$  is not required for cell cycle progression. (A) The distribution of cells in G<sub>0</sub>/G<sub>1</sub>, S and G<sub>2</sub>/M phases. (B) c-myc induction in response to IL-3 stimulation.

10 Figure 26 shows proposed model for the regulation of survival by IL-3.

Figure 27 shows Ser585 phosphorylation and PI 3-K signalling is constitutive in primary human AML cells.

15

## DETAILED DESCRIPTION OF THE INVENTION

In one aspect of the present invention, there is provided a binding motif of a receptor capable of binding a cytoplasmic protein, said binding motif comprising an amino acid sequence wherein at least one amino acid is serine/threonine.

20

Preferably, the serine/threonine residue corresponds to a serine residue at position 601 of the common  $\beta_c$  according to Figure 1 (SEQ ID NO:1).

In a preferred aspect of the present invention, there is provided a binding motif of a receptor capable of binding a cytoplasmic protein, said binding motif comprising an amino acid sequence, a functional equivalent or analogue thereof and wherein at least two (2) of the amino acids are serine.

25

Preferably the binding motif comprises an amino acid sequence including the sequence:

30

-S-X-S/T- (SEQ ID NO:2)

wherein the X is any amino acid.

Applicants have found that the second serine/threonine of the motif is an indicator of the cytoplasmic protein binding motif. However, the motif as a whole is involved in the cytoplasmic binding and requires the serine/threonine residue along with flanking amino acids.

5

Preferably, the motif includes flanking amino acid sequences which may improve the binding of a cytoplasmic protein to the binding motif. More preferably the flanking amino acids are selected from R and X-P (wherein X is any amino acid such that the flanking amino acids individually or co-operatively contribute to the binding motif for binding to a cytoplasmic protein.

10

More preferably the amino acid sequence of the binding motif includes the sequence:

-R-S-X-S/T-X-P- (SEQ ID NO:3)

15 wherein X is any amino acid.

The term "functional equivalent or analogue thereof" as used herein means a sequence which functions in a similar way but may have deletions, additions or substitutions that do not substantially change the activity or function of the sequence.

20

The term "comprising" or "comprises" or variations of the word as used herein is not intended to exclude other additives, components integers or steps.

25 The term "motif" as used herein in relation to the receptor, means a distinctive portion of the receptor but is not intended to include the whole receptor.

The receptor may be any receptor that is capable of binding to an extracellular molecule or protein and which mediates its function through the binding of a cytoplasmic molecule or protein such as 14-3-3 protein, or any cytoplasmic molecule or protein capable of binding a further signaling molecule which activates a cascade of events leading to cell signaling pathways and biological functions such as mitogenesis, proliferation, transformation, differentiation and cell survival, or any other cytoplasmic molecule or protein which does not signal.

30

**Substitute Specification**

This molecule may act as an antagonist. More preferably, the cytoplasmic protein is 14-3-3.

5 Signaling molecules may be molecules involved in cellular pathways such as those pathways involved in proliferation, survival or differentiation. Examples of such pathways may include the JAK/STAT pathway, the ras/MAP kinase pathway or the PI-3-Kinase pathway. All pathways may be involved directly or indirectly with these functions.

10 Preferably the receptor is selected from the group including:

- (1) GM-CSF/IL-3/IL-5 receptor
- (2) IL6 human interleukin-6 receptor beta chain precursor (IL-6R-beta)
- (3) LEPR human leptin receptor precursor (LEP-R) (OB RECEPTOR) (OB-R).
- 15 (4) TNFR2 human tumor necrosis factor receptor 2 precursor (tumor necrosis factor
- (5) VGR1 human vascular endothelial growth factor receptor 1 precursor
- (6) TRK3 human receptor protein-tyrosine kinase TKT precursor (EC 2.7.1.112)
- 20 (7) Q01974 protein-tyrosine kinase transmembrane receptor ROR2 precursor
- (8) FGR1 human basic fibroblast growth factor receptor 1 precursor (BFGF-R)
- (9) Q15426 protein-tyrosine phosphatase, receptor-type, H precursor (EC 3.1.3.48)
- (10) PTPM human protein-tyrosine phosphatase mu precursor (EC 3.1.3.48)
- 25 (R-PTP-MU).
- (11) PDGS human alpha platelet-derived growth factor receptor precursor (EC 2.7.1.112)
- (12) FGR4 human fibroblast growth factor receptor 4 precursor (FGFR-4) (EC 2.7.1.112)
- 30 (13) FGR2 human fibroblast growth factor receptor 2 precursor (FGFR-2) (EC 2.7.1.112)
- (14) Q13635 patched protein homolog (PTC)
- (15) MANR human macrophage mannose receptor precursor.

- (16) LRP2 human low-density lipoprotein receptor-related protein 2 precursor (megalin)
- (17) IDD human integral membrane protein dgcr2/idd precursor (KIAA0163)
- (18) AMFR human autocrine motility factor receptor precursor (AMF receptor) (gp78)
- (19) ACH5 human neuronal acetylcholine receptor protein, alpha-5 chain precursor.
- (20) KKIT human: stem cell growth factor receptor (proto-oncogene tyrosine-protein kinase kit) (C-KIT) (CD117 antigen)
- (21) TPOR human: thrombopoietin receptor precursor (TPO-R) (myeloproliferative leukemia protein (C-MPL). TPOR or MPL.
- (22) TPOR mouse: thrombopoietin receptor precursor (TPO-R) (myeloproliferative leukemia protein) (C-MPL). TPOR or MPL.
- Preferably, the binding motif of the receptor is capable of interacting with a cytoplasmic molecule or protein, or any cytoplasmic molecule or protein capable of binding a further signaling molecule which activates a cascade of events leading to cell signaling pathways and biological functions such as mitogenesis, proliferation, transformation, differentiation and cell survival, or any other cytoplasmic molecule or protein which does not signal. This molecule may act as an antagonist. More preferably, the cytoplasmic protein is 14-3-3.

The 14-3-3 protein is a family of proteins which consists of 7 different isoforms and is expressed ubiquitously from yeast to humans. The ability of 14-3-3 to bind to a number of motifs in a wide range of signaling molecules suggests that 14-3-3 proteins may participate in a number of cell signaling pathways that may include mitogenesis, transformation and survival. Although 14-3-3 has been shown to bind a number of signaling molecules, it has been more difficult to determine how 14-3-3 can regulate signaling events.

30

Preferably the binding motif of a receptor has an amino acid sequence selected from the group including:

- (i) HSRSLP (SEQ ID NO:4)
- (ii) SSSRP (SEQ ID NO:5)

**Substitute Specification**

	(iii)	SNSKP (SEQ ID NO:6)
	(iv)	SDSSP (SEQ ID NO:7)
	(v)	SISAP (SEQ ID NO:8)
	(vi)	SLSLP (SEQ ID NO:9)
5	(vii)	SASTP (SEQ ID NO:10)
	(viii)	SPSFP (SEQ ID NO:11)
	(ix)	SNSQP (SEQ ID NO:12)
	(x)	SVSSP (SEQ ID NO:13)
	(xi)	STSVP (SEQ ID NO:14)
10	(xii)	SKSPP (SEQ ID NO:15)
	(xiii)	SRSQP (SEQ ID NO:16)
	(xiv)	SSSLP (SEQ ID NO:17)
	(xv)	SSSGP (SEQ ID NO:18)
	(xvi)	SSSFP (SEQ ID NO:19)
15	(xvii)	SPSYP (SEQ ID NO:20)
	(xviii)	SGSLP (SEQ ID NO:21)
	(xix)	SQSSP (SEQ ID NO:22)
	(xx)	SPSLP (SEQ ID NO:23)
	(xxi)	SGSTP (SEQ ID NO:24)
20	(xxii)	SVSPP (SEQ ID NO:25)
	(xxiii)	SGSGP (SEQ ID NO:26)
	(xxiv)	SLGSSP (SEQ ID NO:27)
	(xxv)	SSSQP (SEQ ID NO:28)
	(xxvi)	KSSERTP (SEQ ID NO:29)
25	(xxvii)	KSSESTP (SEQ ID NO:30)

or a functional equivalent or analogue thereof.

The binding capacity of the motif may be analysed by any binding studies or experiments available to the skilled addressee. Such experiments may include measuring the binding ability of a designated cytoplasmic protein to the binding motif. For instance electrophoretic mobility shift assays (EMSA or band shift assays) or foot print assays or pull down experiments are available to measure specific binding.

Hence the binding motif can be identified by the presence of a, serine residue preferably in an amino acid sequence as described above, and the ability to bind a designated cytoplasmic protein. The designated cytoplasmic protein may be 14-3-3 protein, or any cytoplasmic protein capable of binding a further signaling molecule which activates a cascade of events leading to cell signaling pathways and biological functions such as mitogenesis, proliferation, transformation, differentiation and cell survival. More preferably, the cytoplasmic protein is 14-3-3.

10 Preferably, the receptor is the GM-CSF/IL-3/IL-5 receptor which includes the common beta chain ( $\beta_c$ ). It is found that the cytokines GM-CSF, IL-3 and IL-5 signal their actions through the surface receptor via the  $\beta_c$ . Most preferably, the binding motif comprises a sequence which includes amino acids HSRSLP (SEQ ID NO:4) corresponding to amino acids 598 to 603 of the common  $\beta_c$  according to Figure 1 (SEQ ID NO:1) a functional equivalent or analogue thereof.

The common  $\beta$  chain ( $\beta_c$ ) is a component of a cytokine receptor and is part of a signaling subunit of the receptor. It is thought that the cytokine signals its functions through the  $\beta_c$ , initiating events which cascade and culminate in an identifiable biological function such as cell survival, proliferation, differentiation and mature cell effector functions. However, the present invention is not limited to motifs of the  $\beta_c$  but includes motifs of receptors having similar sequences to the  $\beta_c$  and including a serine/threonine residue.

25 The region or motif comprising amino acids 598 to 603 of the common  $\beta_c$  may include <sup>598</sup>HSRSLP<sup>603</sup> (SEQ ID NO:31) which preferably interacts with a cytoplasmic protein selected from the group including 14-3-3 protein, WW-domain of the prolyl isomerase, Pin1, and the ubiquitin ligase, NEDD4 or any cytoplasmic protein capable of binding a further signaling molecule which activates a cascade of events leading to cell signaling pathways and biological functions such as mitogenesis, proliferation, transformation, differentiation and cell survival. However the present invention is not limited to this sequence but includes other equivalent sequences capable of performing the same function.

Other binding motifs of receptors according to the present invention include amino acid sequences of:

- 5 Stem Cell Growth Factor Receptor (C-Kit) (Proto-Oncogene Tyrosine- Protein Kinase Kit) (C-KIT) (CD 117 Antigen), preferably including amino acids 863 to 869 according to Figure 2 (SEQ ID NO:32) or amino acid residues 965 to 969 according to Figure 2 (SEQ ID NO:32) or a functional equivalent or analogue thereof.
- 10 Thrombopoietin Receptor Precursor (TPO-R) (Myeloproliferative Leukemia Protein) (C-MPL). (TPOR or MPL) preferably including amino acids 573 to 579 according to Figure 3 (SEQ ID NO:33) or a functional equivalent or analogue thereof.
- 15 Thrombopoietin Receptor Precursor (TPO-R) (Myeloproliferative Leukemia Protein) (C-MPL). (TPOR or MPL) preferably including amino acids 564 to 570 according to Figure 4 (SEQ ID NO:34) or a functional equivalent or analogue thereof.
- 20 IL6B HUMAN interleukin-6 receptor beta chain precursor (IL-6R-BETA), preferable including amino acids 735- 739 having the sequence SSSRP (SEQ ID NO:5) or a functional equivalent or analogue thereof
- 25 LEPR HUMAN leptin receptor precursor (LEP-R) (OB receptor) (OB-R), preferably including amino acids 991- 995 having the sequence SNSKP (SEQ ID NO:6) or a functional equivalent or analogue thereof.
- 30 TNF2 HUMAN tumor necrosis factor receptor 2 precursor (tumor necrosis factor) preferably including amino acids 368- 372 having the sequence SDSSP (SEQ ID NO:7) or a functional equivalent or analogue thereof.

VGR1 HUMAN vascular endothelial growth factor receptor 1 precursor, preferably including amino acids 1197- 1201 having the sequence SISAP (SEQ ID NO:8) or a functional equivalent or analogue thereof.

- 5 TRK3 HUMAN receptor protein-tyrosine kinase TKT precursor (EC 2.7.1.112), preferably including amino acids 444- 448, having the sequence SLSLP (SEQ ID NO:9) or a functional equivalent or analogue thereof.

- 10 Q01974 protein-tyrosine kinase transmembrane receptor ROR2 precursor, preferably including amino acids 435- 439, having the sequence SASTP (SEQ ID NO:10) or a functional equivalent or analogue thereof.

- 15 FGR1 HUMAN basic fibroblast growth factor receptor 1 precursor (BFGF-R), preferably including amino acids 777- 781, having the sequence SPSFP (SEQ ID NO:11) or a functional equivalent or analogue thereof.

- 20 Q15426 protein-tyrosine phosphatase, receptor-type, H precursor (EC 3.1.3.48), preferably including amino acids 1082- 1086, having the sequence SNSQP (SEQ ID NO:12) or a functional equivalent or analogue thereof.

- PTPM HUMAN protein-tyrosine phosphatase MU precursor (EC 3.1.3.48) (R-PTP-MU), preferably including amino acids 818- 822, 833- 837, 1082- 1086 having the sequences SVSSP (SEQ ID NO:13), STSVP (SEQ ID NO:14), SKSPP (SEQ ID NO:15) or functional equivalents or analogues thereof.

- 25 PGDS HUMAN alpha platelet-derived growth factor receptor precursor (EC 2.7.1.112), preferably including amino acids 616- 620 having the sequence SRSQP (SEQ ID NO:16) or a functional equivalent or analogue thereof.

- 30 FGR4 HUMAN fibroblast growth factor receptor 4 precursor (FGFR-4) (EC 2.7.1.112), preferably including amino acids 439- 443, 791- 795 having the sequences SSSGP (SEQ ID NO:18), SSSFP (SEQ ID NO:19) or functional equivalents or analogues thereof.

FGR2 HUMAN fibroblast growth factor receptor 2 precursor (FGFR-2) (EC 2.7.1.112), preferably including amino acids 780- 784 having the sequence SPSYP (SEQ ID NO:20) or a functional equivalent or analogue thereof.

- 5 Q13635 patched protein homolog (PTC), preferably including amino acids 1290-1294 having the sequence SGSLP (SEQ ID NO:21) or a functional equivalent or analogue thereof.

- 10 MANR HUMAN macrophage mannose receptor precursor, preferably including amino acids 1432- 1436 having the sequence SQSSP (SEQ ID NO:22) or a functional equivalent or analogue thereof.

- 15 LRP2 HUMAN low-density lipoprotein receptor-related protein 2 precursor (megalin), preferably including amino acids 4616- 4620 having the sequence SPSLP (SEQ ID NO:23) or a functional equivalent or analogue thereof.

- 20 IDD HUMAN integral membrane protein DGCR2/IDD precursor (KIAA0163), preferably including amino acids 526- 530 having the sequence SGSTP (SEQ ID NO:24) or a functional equivalent or analogue thereof.

- AMFR HUMAN autocrine motility factor receptor precursor (AMF receptor) (GP78), preferably including amino acids 203- 207 having the sequence SVSPP (SEQ ID NO:25) or a functional equivalent or analogue thereof.

- 25 ACH5 HUMAN neuronal acetylcholine receptor protein, alpha-5 chain precursor, preferably including amino acids 382-386 having the sequence SGSGP (SEQ ID NO:26) or a functional equivalent or analogue thereof.

- 30 In another aspect of the present invention there is provided a phosphorylated binding motif of a receptor capable of binding a cytoplasmic protein, said binding motif comprising an amino acid sequence wherein at least one amino acid is serine/threonine and wherein the serine residue is phosphorylated.

Preferably, the serine residue corresponds to a serine residue at position 601 of the common  $\beta_c$  according to Figure 1 (SEQ ID NO:1).

In another aspect of the present invention, there is provided a phosphorylated  
 5 binding motif of a receptor capable of binding a cytoplasmic protein, said binding motif comprising an amino acid sequence, a functional equivalent or analogue thereof and wherein at least two (2) of the amino acids are serine and wherein at least one serine residue of the motif is phosphorylated.

10 Preferably the binding motif comprises an amino acid sequence including the sequence:

-S-X-S/T- (SEQ ID NO:2)

wherein the X is any amino acid.

15 Applicants have found that the second serine/threonine motif is an indicator of the cytoplasmic protein binding motif. However, the motif as a whole is involved in the cytoplasmic binding and requires the serine/threonine residue along with flanking amino acids.

20 Preferably, the motif includes flanking amino acid sequences which may improve the binding of a cytoplasmic protein to the binding motif. More preferably the flanking amino acids are selected from R and X-P (wherein X is any amino acid) such that the flanking amino acids individually or co-operatively contribute to the binding motif for binding to a cytoplasmic protein.

25

More preferably the amino acid sequence of the binding motif includes the sequence:

-R-S-X-S/T-X-P- (SEQ ID NO:3)

wherein X is any amino acid.

30

The motif must have at least one serine residue. Preferably there are two. Preferably, the second serine residue from the 5' end of the motif is phosphorylated.

Preferably, the receptor is selected from the group of receptors described above and the amino acid sequence is any one of the binding motifs described above.

- In a further preferred aspect, there is provided a binding motif of a GM-CSF/IL-3/IL-5 receptor capable of binding a cytoplasmic protein, said binding motif comprising an amino acid sequence including the sequence <sup>598</sup>HSRSLP<sup>603</sup> (SEQ ID NO:31) of the GM-CSF/IL-3/IL-5 receptor or a functional equivalent or analogue thereof wherein at least Ser<sup>601</sup> is capable of being phosphorylated.
- In a further preferred aspect, there is provided a phosphorylated binding motif of a GM-CSF/IL-3/IL-5 receptor capable of binding a cytoplasmic protein, said binding motif comprising an amino acid sequence including the sequence <sup>598</sup>HSRSLP<sup>603</sup> (SEQ ID NO:31) of the GM-CSF/IL-3/IL-5 receptor or a functional equivalent or analogue thereof wherein at least Ser<sup>601</sup> is phosphorylated.

- More preferably, the binding motif binds to the cytoplasmic protein 14-3-3.
- It is also preferred that other receptors as described above can be phosphorylated and induced to bind a cytoplasmic protein such as 14-3-3 by phosphorylation preferably of the second serine residue from the 5' end of the motif.

- In another aspect of the present invention, there is provided a method of phosphorylating a binding motif of a receptor capable of binding a cytoplasmic protein, said binding motif comprising an amino acid sequence of, a functional equivalent or analogue thereof and wherein at least one amino acid is serine, said method comprising binding a triggering molecule to the receptor.

- Preferably, the serine residue corresponds to a serine residue at position 601 of the common  $\beta_c$  according to Figure 1 (SEQ ID NO:1).

In another aspect of the present invention, there is provided a method of phosphorylating a binding motif of a receptor capable of binding a cytoplasmic protein, said binding motif comprising an amino acid sequence or, a functional

**Substitute Specification**

equivalent or analogue thereof and wherein at least two (2) of the amino acids are serine, said method comprising binding a triggering molecule to the receptor.

Preferably, the binding motif is any one of the motifs described above.

5

In a preferred aspect, phosphorylation of the binding motif is caused by the binding of a triggering molecule to its corresponding receptor. Triggering molecules may be cytokines which bind to cytokine receptors. Preferably the receptor is a heterodimeric receptor. More preferably it is a GM-CSF/IL-5/IL-3  
10 receptor bound by a GM-CSF, IL-5 or IL-3 cytokine. Other triggering molecules may be the corresponding triggering molecule that binds to any one of the receptors listed above.

Preferably the binding motif is as described above.

15

It has been found by the applicants that any triggering molecule which binds to a receptor or receptor signaling system may be capable of causing phosphorylation of the binding motif. Preferably the triggering molecule is a cytokine which binds to a homodimeric or heterodimeric receptor prior to phosphorylation of the binding  
20 motif. Preferably the cytokine binds to a heterodimeric cytokine receptor. The heterodimeric cytokine receptor may comprise two (or three) subunits which subserve distinct and specialised functions. These subunits include the major ligand binding subunit ( $\alpha$  subunit) and the signaling subunit which may comprise a  $\beta$  or  $\delta$  subunit. The signaling subunit may recognise several cytokines on the  $\alpha$   
25 subunit which can then transduce signals from the cytokines into the cell.

The common beta chain ( $\beta_c$ ) is found in the receptor signalling systems of cytokines including granulocyte macrophage colony stimulating factor (GM-CSF), interleukin-3 (IL-3) and interleukin-5 (IL-5). In this system, preferably the binding  
30 motif comprises an amino acid sequence including <sup>598</sup>HSRSLP<sup>603</sup> (SEQ ID NO:31) on the  $\beta_c$ . More preferably, this sequence is phosphorylated upon binding of GM-CSF, IL-3 or IL-5 to the receptor. More preferably Ser<sup>601</sup> is

phosphorylated particularly when GM-CSF, IL-3 or IL-5 bind to their corresponding receptors.

5 However, other triggering molecules can cause phosphorylation of an equivalent region of the receptor. For instance, the molecule which binds to the receptor (as listed above) may cause phosphorylation to the binding motif.

In another aspect of the present invention, there is provided a method of binding a cytoplasmic protein to a receptor, said method comprising:

10

phosphorylating a binding motif of a receptor as described above, a functional equivalent or analogue thereof; and

subjecting the binding motif of the receptor to a cytoplasmic protein.

15

Although not wishing to be limited by theory, it is perceived that the phosphorylation of the binding motif may improve the binding of a cytoplasmic protein to the binding motif so that when the cytoplasmic protein is reacted with the motif, or equivalent thereof, binding may occur to bring other cytoplasmic  
20 proteins or signaling molecules into close proximity to the receptor. Phosphorylation may occur by any means which transfers a phosphoryl (phosphate) group to the cytoplasmic binding motif.

The cytoplasmic protein may be 14-3-3 protein, or any cytoplasmic protein  
25 capable of binding a further signaling molecule which activates a cascade of events leading to cell signaling pathways and biological functions such as mitogenesis, proliferation, transformation, differentiation, cell survival, chemotaxis, motility, enhanced phagocytosis, bacterial killing, superoxide production and cytotoxicity.

30

In another aspect of the present invention, there is provided a method of activating cellular activities said method including:

regulating the activation of phosphorylation of a binding motif of a receptor as described above, a functional equivalent or analogue thereof; and

5       subjecting the binding motif to a cytoplasmic protein wherein said cytoplasmic protein is associated with cellular activities.

Preferably the cytoplasmic protein is 14-3-3 protein, or any cytoplasmic protein capable of binding a further signaling molecule which activates a cascade of events leading to cell signaling pathways and biological functions such as  
10       mitogenesis, proliferation, transformation, differentiation cell survival, chemotaxis, motility, enhanced phagocytosis, bacterial killing, superoxide production and cytotoxicity. Preferably the cytoplasmic binding protein is 14-3-3.

The 14-3-3 molecule binds not only to the cytoplasmic binding motif (as found by  
15       the applicants) but has the ability to bind to a wide range of signaling molecules and to participate in a number of cell signaling pathways resulting in mitogenesis, transformation, differentiation cell survival, chemotaxis, motility, enhanced phagocytosis, bacterial killing, superoxide production and cytotoxicity.

20       Once 14-3-3 or an equivalent binds to the binding motif of the receptor, its ubiquitous nature can bind cytoplasmic proteins involved in signaling pathways which activate these pathways. For instance, not being limited by theory and by example, it has now been found by the Applicants that cytokines such as GM-CSF, IL-3 or IL-5, will bind to the  $\beta_c$  of the receptor. The binding motif of the  
25       receptor is then phosphorylated and preferably phosphorylates the Ser<sup>601</sup> or equivalent residue. 14-3-3 can bind to the phosphorylated motif thereby positioning the 14-3-3 close to the receptor for further binding of cytoplasmic proteins involved in cell signaling (signaling molecules) for cellular activities such as proliferation, differentiation, cell survival, chemotaxis, motility, enhanced  
30       phagocytosis, bacterial killing, superoxide production and cytotoxicity.

In yet another aspect of the present invention there is provided a method of regulating cellular activities, said method including:

regulating the phosphorylation of a binding motif of a receptor as described above, a functional equivalent or analogue thereof;

5       subjecting the binding motif to a cytoplasmic protein to bind the cytoplasmic protein to the binding motif; and

activating a cell signaling pathway by interacting the bound cytoplasmic protein with a signaling molecule involved in the pathway.

10       Preferably, the cytoplasmic protein is 14-3-3 protein, or any cytoplasmic protein capable of binding a further signaling molecule which activates a cascade of events leading to cell signaling pathways and biological functions such as mitogenesis, proliferation, transformation, differentiation, cell survival, chemotaxis, motility, enhanced phagocytosis, bacterial killing, superoxide production and cytotoxicity. Preferably the cytoplasmic binding protein is 14-3-3.

15

There are many signaling molecules involved in cellular pathways leading to cellular activity. However, it is preferred in the present invention to provide a molecule that binds to a phospho-serine bound 14-3-3 molecule such that a pathway is coupled to the motif or equivalent unit in a receptor and brought into  
20       close proximity to downstream signaling proteins at, or near, the cell membrane. Cellular activities may include cell survival, proliferation, transformation, differentiation, mitogenesis, chemotaxis, motility, enhanced phagocytosis, bacterial killing, superoxide production and cytotoxicity.

25       For regulating cell survival, it is preferred to activate the PI-3-kinase pathway using a PI-3 kinase bound to a phosphoserine bound 14-3-3. This may be shown in Figure 18 or Figure 26. Figure 26 shows proposed model for the regulation of survival by IL-3. Binding of IL-3 to the IL-3 receptor, composed of a ligand specific  $\alpha$ -chain ( $\alpha$ ) and a common  $\beta$ -chain ( $\beta_c$ ), results in receptor  
30       oligomerization (only one  $\alpha$ -chain and one  $\beta$ -chain are shown for simplicity). Receptor oligomerization results in the activation of tyrosine kinases which results in tyrosine phosphorylation of  $\beta_c$  (P-Y) and the recruitment of SH2- and PTB-binding proteins (not shown). In addition, activation of PKA results in the

phosphorylation of Ser601 of  $\beta_c$  (S-P). Ser601 phosphorylation allows the recruitment of 14-3-3, which in turn recruits PI 3-kinase (PI 3-K) either directly through the p110 or p85 subunits or indirectly through an additional adaptor molecule(s). These receptor proximal events identified in the current studies  
5 which result in the activation of PI 3-kinase are then likely to couple to a downstream pathway involving Akt and BAD. BAD phosphorylation results in 14-3-3 binding and sequestration of BAD in the cytoplasm and suppression of apoptosis (survival). In the absence of cytokine, BAD remains unphosphorylated and translocates to the mitochondria where the events leading to apoptosis are  
10 triggered (death).

Phosphorylation of the motif may be regulated by any means which results in inhibition or activation of the phosphorylation of the cytoplasmic protein binding motif particularly the Ser<sup>601</sup> residue. Preferably, the phosphorylation is induced  
15 by a triggering molecule such as a cytokine selected from the group including GM-CSF, IL-3 or IL-5. More preferably for cell survival, it is induced by IL-3. In this case, the  $\beta_c$  is phosphorylated. More preferably the binding motif comprising the amino acid sequence HSRSLP (SEQ ID NO:4) is phosphorylated. More preferably the second serine from the 5' end is phosphorylated. In  $\beta_c$ , this  
20 correlates to Ser<sup>601</sup>.

Regulation of cell survival may include enhancing or reducing cell survival or even causing cell death. This may be achieved by enhancing or inhibiting any of the steps described above. For instance enhancing phosphorylation of the binding  
25 motif may enhance survival. Alternatively, inhibiting phosphorylation may inhibit cell survival.

In another aspect of the present invention, there is provided a method of inhibiting cell survival, said method including inhibiting the binding of a cytoplasmic protein  
30 to a binding motif of a receptor as described above.

Preferably the cytoplasmic protein is 14-3-3.

Preferably the receptor is the GM-CSF/IL-5/IL-3 receptor and the triggering molecule is IL-3, although a phosphorylation event which phosphorylates <sup>601</sup>Ser may also trigger the binding of 14-3-3 to the motif.

- 5 For cell survival or cell activation, it is preferred that the binding motif is as described above.

Antagonists that bind to the receptor motif in either the phosphorylated or unphosphorylated form may be useful to inhibit cell survival or activation.

- 10 Preferably antagonists may be useful to inhibit cell survival or activation by preventing phosphorylation preferably by preventing serine phosphorylation of the  $\beta_c$  or equivalent thereby preventing the cytoplasmic protein binding to the binding motif. Alternatively, they may prevent the interaction of a signaling molecule binding to a phosphoserine bound 14-3-3 or equivalent. Prevention of
- 15 phosphorylation of the  $\beta_c$  or binding motif as described above may be by inhibition of the specific kinases involved in the phosphorylation of the serine/threonine residue or it may include mutation of the binding motif to prevent the cytoplasmic protein such as 14-3-3 from binding and activating cell cycle pathways. Kinase inhibitors such as H89 which binds to PKA may be used. Preferably, cell
- 20 permeable kinase inhibitors are used. Preferably the signaling molecule is a PI-3-kinase involved in the PI-3-kinase pathway which leads to cell survival or cell activation.

- Antagonists may include antibodies, small peptides, small molecules, peptide
- 25 mimetics or any type of molecule known to those skilled in the art that are directed to the cytoplasmic binding motif so as to prevent attachment of cytoplasmic proteins such as 14-3-3 to a phosphoserine residue or a signaling molecule. Antibodies may be generated in response to any of the binding motifs described above by methods known and available to the skilled addressee.

30

Hence, the antagonists as described may be useful as cancer therapeutics to prevent cell survival of cancer cells or cell activation such as myeloid cell activation and may be useful for preventing or treating leukaemia such as acute

myeloid leukaemia (AML). Other uses of antagonists may be in prevention and treatment of inflammatory diseases.

- Applicants have also found that the <sup>601</sup>Ser in  $\beta_c$  of acute myeloid leukaemia (AML) is constitutively phosphorylated (see Figure 19). Hence by preventing phosphorylation of the <sup>601</sup>Ser, further binding of 14-3-3 to the binding motif of  $\beta_c$  may be prevented thereby further preventing the binding of PI-3-kinase which interacts with the PI-3-kinase pathway to activate cell survival. This may be useful to prevent those functions related to cell activation, particularly myeloid cell activation. The functions may be selected from the group including chemotaxis, motility, enhanced phagocytosis, bacterial killing, superoxide production and cytotoxicity. These functions may also contribute to inflammation including, but not limited to, asthma and rheumatoid arthritis.
- Accordingly, there is provided a method of inhibiting cell activation, said method including inhibiting the binding of a cytoplasmic protein to a binding motif of a receptor as described above.

- Accordingly this method of interaction may be a useful tool for a method of treating or preventing cell proliferative diseases such as AML or cancer.

- Targeting may be by way of the use of antagonists as described above or by any means that prevents activation of cell cycles via the binding motif described in the present invention. Targeting may be by blocking or mutating the motif.

- Techniques such as gene therapy may also be employed which targets or removes the binding motif.

- In another aspect, there is also provided a method of treating a cytokine mediated condition said method comprising:

regulating the activation of phosphorylation of a binding motif of a receptor as described above, a functional equivalent or analogue thereof.

- 5 The cytokine mediated condition is a condition which requires a cytokine to bind to its receptor to induce a cellular activity. By regulating the activator, cellular action may be activated to increase the phosphorylation or to decrease phosphorylation. Preferably, the cytokine mediated condition is a GMCSF/IL-5 mediated condition and the binding motif includes the amino acid sequence
- 10 <sup>598</sup>HSRSLP<sup>603</sup> (SEQ ID NO:31) on the  $\beta_c$ .

The present invention will now be more fully described with reference to the following examples. It should be understood, however, that the description following is illustrative only and should not be taken in any way as a restriction on

15 the generality of the invention described above.

## EXAMPLE 1

### **BINDING OF 14-3-3 TO A COMMON BETA CHAIN ( $\beta_c$ )**

- (a) **Mutagenesis of human  $\beta_c$  and expression plasmid constructs.**
- 20 Substitution mutations of two sequences within the cytoplasmic domain of the human  $\beta_c$  cDNA were constructed using oligonucleotide-directed mutagenesis (Altered-sites, Promega, Sydney, NSW, Australia) as described in Wood Cock, J.M. et al (1994) EMBO, 13, 5176. Both mutants were essentially poly-alanine substitutions. Mutagenesis oligonucleotides encoding non-alanine residues were
- 25 included to facilitate restriction enzyme screening of mutant clones. The first motif was <sup>598</sup>HSRSLP<sup>603</sup> (SEQ ID NO:31) mutated to <sup>598</sup>EFAAAA<sup>603</sup> (SEQ ID NO:43) and the second was <sup>820</sup>RSKPSSP<sup>826</sup> (SEQ ID NO:37) mutated to <sup>820</sup>EFAAAAAA<sup>826</sup> (SEQ ID NO:38). The point mutant S601A was also constructed, however this mutant created a cryptic proteolytic site in  $\beta_c$  and was not able to be
- 30 used. The mutations were confirmed by nucleotide sequencing and the mutant  $\beta_c$  cDNAs subcloned into the eukaryotic expression vector *pcDNA1* (Invitrogen, San Diego, CA). The  $\beta_c$  deletion mutant cDNAs were a kind gift of Dr A. Miyajima.

- (b) **GM-CSF and IL-3.** Recombinant human IL-3 and GM-CSF were produced in *E.coli* essentially as described in Barry, S.C. et al (1994) J. Biol chem, 269, 8488 and Hercus, T.R. et al (1994) Proc. Natl. Acad. Sci., 91, 5838. Cytokine purity and quantitation was determined by HPLC analysis and Coomassie staining of SDS-PAGE separated proteins. The activity of the cytokines based on the ED<sub>50</sub> values in a TF-1 proliferation assay (Kitamura, T. et al (1989) J. Cell Physiol, 140, 323) was 0.03ng/ml for GM-CSF and 0.1ng/ml for IL-3.
- (c) **Antibodies.** The monoclonal antibodies 8E4 and 1C1 directed against the  $\beta_c$  were generated as previously described in Stomski, F.C. et al (1998) J. Biol. Chem., 273, 1192. The anti- phospho- <sup>601</sup>Ser $\beta_c$  antibody was raised by immunising New Zealand white rabbits with the phosphorylated CLGPPHSRSLPDILG (SEQ ID NO:39) peptide conjugated to keyhole limpet hemocyanin (Sigma). The anti-peptide antibody was firstly affinity purified with the immunising peptide conjugated to sepharose and then absorbed with the nonphosphorylated CLGPPHSRSLPDILG (SEQ ID NO:39) peptide conjugated to sepharose. The specificity of the anti-phospho- <sup>601</sup>Ser $\beta_c$  antibody was verified by dot immunoblots against the CLGPPHSRSLPDILG (SEQ ID NO:39) peptide either non phosphorylated or serine phosphorylated form and a scrambled peptide CLPLSGPDSHIRGPL (SEQ ID NO:42). The corresponding phosphorylated serine in each peptide is underlined. Peptides were synthesised by Chiron Mimotopes, Melbourne, Australia. The anti-14-3-3z antibody was kindly provided by Dr A. Aitken.
- (d) **Cell culture and DNA transfection.** The HEK293T cell line was maintained in RPMI-1640 supplemented with 10 % v/v fetal calf serum (FCS). On the day before transfection,  $1.4 \times 10^6$  cells were plated into 6 cm tissue culture dishes to adhere overnight. Four hours after a medium change, 6 mg of wild type or mutated  $\beta_c$  cDNA was added to cells in the form of a calcium phosphate precipitate (Graham, F.L. et al (1973) Virology, 52, 456), and the cells were placed in an incubator for 4-6 h to permit the uptake of the DNA-calcium phosphate precipitate. The cells were then washed, replated and placed in the incubator for 48h prior to cytokine treatment. M1 cell line expressing GM-CSF

receptor alpha chain and  $\beta_c$  wild type was maintained in RPMI-1640 supplemented with 10 % v/v FCS. The M1 cell line was kindly provided by Dr N. Nicola.

5 (e) **Surface marker analysis by flow cytometry.** Expression of receptors on transfected cells was verified by flow cytometry. Briefly, cells were incubated with the anti- $\beta_c$  MAb (1C1) (Stomski, F.C. et al (1996) Mol. Cell. Biol, 16, 3035) or anti-GM-CSFRa MAb (4H1) (Stomski, F.C. et al (1998) J. Biol. Chem. 273, 1192) for 20 minutes on ice, washed, and subsequently incubated with fluorescein  
10 isothiocyanate (FITC)-conjugated anti-mouse IgG antibody (Silenus Laboratories, Hawthorn, Victoria, Australia) for 20 minutes on ice. Cells were then washed and resuspended in FACS FIX and analysed using a Profile II (Coulter Electronics).

(f) **Immunoprecipitations.** Cells were lysed in lysis buffer [150mM NaCl, 15 10mM Tris-HCl (pH 7.4), 1% Digitonin with protease inhibitors (10mg/ml leupeptin, 2mM phenylmethanesulfonyl fluoride, 10mg/ml aprotinin) and 2mM sodium vanadate] for 30 mins at 4°C followed by centrifugation of the lysate for 15 mins at 12,000g at 4°C. Following a 1 hour preclearance with Protein-A-sepharose (Pierce, Rockford, IL) at 4°C, the supernatant was incubated for 2  
20 hours with 5mg/ml antibody. Protein-immunoglobulin complexes were captured by incubation for 1 hour with Protein-A-sepharose followed by 6 subsequent washes in lysis buffer. Samples were boiled for 5 mins in SDS sample load buffer in the presence or absence of 2-mercaptoethanol before separating immunoprecipitated proteins by SDS-PAGE.

25

(g) **Precipitations.** Cells were lysed in lysis buffer for 30 mins at 4°C followed by centrifugation of the lysate for 15 mins at 12,000g 4°C. Following a 1 hour preclearance with GST-sepharose at 4°C, the supernatant was incubated for 2  
30 hours with GST-14-3-3-sepharose followed by 3 subsequent washes in lysis buffer. Samples were boiled for 5 mins in SDS sample load buffer in the presence of 2-mercaptoethanol before separating precipitated proteins by SDS-PAGE.

(h) **Competition of precipitations and immunoprecipitations by peptides.**

Cell lysates were precipitated or immunoprecipitated in the presence of various concentrations of the following peptides:  $\beta_c$  peptide sequence CLGPPHSRSLPDILG (SEQ ID NO:39) either non phosphorylated or serine  
 5 phosphorylated and a scrambled peptide CLPLSGPDSHIRGPL (SEQ ID NO:42). Raf1 peptides corresponding to the sequence CLSQRQRSTSTPNVHM (SEQ ID NO:40) were also used and were either non phosphorylated or serine phosphorylated. The corresponding phosphorylated serine in each peptide is underlined. Peptides were synthesised by Chiron Mimotopes, Melbourne,  
 10 Australia. The presence of  $\beta_c$  in either the immunoprecipitation or precipitation experiment was determined by Western blotting with anti- $\beta_c$  antibody (MAb 1C1).

(i) **SDS-Polyacrylamide Gel Electrophoresis, Immunoblot and ECL**

Immunoprecipitated proteins separated by SDS-PAGE were transferred to  
 15 nitrocellulose membrane by electroblotting. Dot blots of peptides were performed by spotting either 10 or 100 ng of each peptide onto nitrocellulose membranes. Routinely, nitrocellulose membranes were blocked in a solution of PBS/0.05% (v/v) Tween 20 (PBT) containing 1% (w/v) blocking reagent 1096 176 (Boehringer Mannheim) and probed with anti-  $\beta_c$  (1C1), anti-14-3-3z<sup>33</sup> or anti-phospho-  
 20 <sup>601</sup>Ser $\beta_c$  followed by either anti-mouse or rabbit peroxidase conjugated antibodies. Immunoreactive proteins were detected by chemiluminescence using the ECL kit (Amersham, Little Chalfont, U.K.) following the manufacturer's instructions.

25 (j) **Binding of the <sup>125</sup>I-labeled 14-3-3z to Synthetic Peptides.** The recombinant 14-3-3z protein was <sup>125</sup>I-labeled using IODOBEADS (Pierce). The synthetic peptides were solubilised in distilled water and then diluted to 50mg/ml in 0.1 M NaHCO<sub>3</sub>, pH 9.2. The peptides were coated onto microtiter wells (Immunolon II Removawells, Dynatech Laboratories, Chantilly, VA) by incubation  
 30 at 22°C for 6 h and then 4°C overnight. The peptide coated microtiter wells were blocked at 22°C with 5% bovine serum albumin for 2h and then with <sup>125</sup>I-labeled 14-3-3z protein for 2h. After three washes, microtiter well-bound radioactivity were estimated in a g-counter.

The results of these experiments show that that firstly,  $\beta_c$  interacts with 14-3-3, and secondly, that the region of interaction lies between amino acids 544 and 626.

5

## EXAMPLE 2

### **BINDING OF 14-3-3 TO <sup>598</sup>HSRSLP<sup>603</sup> MOTIF OF $\beta_c$**

We then examined whether 14-3-3 interacted with  $\beta_c$  via the <sup>598</sup>HSRSLP<sup>603</sup> motif which lies within the 544-626 region identified in Figure 5. A substitution mutant  
 10 ( $\beta_c$ - <sup>598</sup>HSRSLP<sup>603</sup> (SEQ ID NO:31)→EFAAAA(SEQ ID NO:43)) and a point mutant ( $\beta_c$ -601S→A) in the putative 14-3-3 binding site were constructed as well as a control mutant ( $\beta_c$  <sup>820</sup>RSKPSSP<sup>826</sup>(SEQ ID NO:37)→EFAAAA(SEQ ID NO:38)). These mutants were expressed in HEK 293T cells and examined for their ability to interact with GST-14-3-3 in pull-down experiments. While wild type  
 15  $\beta_c$  and the control mutant  $\beta_c$  interacted with GST-14-3-3, no detectable interaction was observed for the  $\beta_c$  <sup>598</sup>HSRSLP<sup>603</sup> (SEQ ID NO:31)→EFAAAA (SEQ ID NO:43) mutant (Figure 6). These results indicate that 14-3-3 associates with  $\beta_c$  via the <sup>598</sup>HSRSLP<sup>603</sup> sequence (SEQ ID NO:31).

20

## EXAMPLE 3

### **ROLE OF <sup>601</sup>SER IN $\beta_c$ INTERACTION WITH 14-3-3**

14-3-3 is known to be a phospho-serine binding protein which interacts with the RSXSXP motif (SEQ ID NO:3), where S is phosphorylated. We tested whether  
<sup>601</sup>Ser phosphorylation within the <sup>598</sup>HSRSLP<sup>603</sup> (SEQ ID NO:31) motif would be  
 25 required for 14-3-3 association. We synthesised a  $\beta_c$  peptide containing a non-phosphorylated <sup>601</sup>Ser ( C<sup>594</sup>LGPPHSRSLPDILG<sup>607</sup>; SEQ ID NO:39) and a  $\beta_c$  peptide containing a phosphorylated <sup>601</sup>Ser and examined their ability to inhibit  $\beta_c$  interaction with GST-14-3-3 in a pull-down experiment. While the peptide containing phosphorylated <sup>601</sup>Ser inhibited  $\beta_c$  association with GST-14-3-3, no  
 30 inhibition of association was observed for the peptide containing the non-phosphorylated <sup>601</sup>Ser (Figure 4; SEQ ID NO:34). As a comparison, nonphosphorylated and phosphorylated peptides corresponding to the 14-3-3 binding site in Raf-1 were also tested. We found that the serine phosphorylated

**Substitute Specification**

Raf-1 peptide was also able to inhibit  $\beta_C$  association with 14-3-3 while the non-phosphorylated peptide did not (Figure 4; SEQ ID NO:34). Furthermore, the ability of the  $\beta_C$  phosphorylated peptide to inhibit the association of  $\beta_C$  with 14-3-3 was dose-dependent and specific as another phosphorylated peptide with

5 sequence corresponding to a different region of  $\beta_C$  failed to inhibit this association (Figure 8). Direct binding experiments and Scatchard analysis demonstrated that the phosphorylated peptide ( $^1\text{C}^{594}\text{LGPPHSRSLPDILG}^{607}$ ; SEQ ID NO:39) bound to 14-3-3 with an affinity of approximately 150nM (Figure 9). These experiments show that the  $^{598}\text{HSRSLP}^{603}$  (SEQ ID NO:31) sequence in  $\beta_C$  directly binds to 14-

10 3-3 and that this binding is dependent on  $^{601}\text{Ser}$  being phosphorylated.

#### EXAMPLE 4

##### IN VIVO REGULATION OF $^{601}\text{Ser}$ PHOSPHORYLATION

Having identified the requirement for  $\beta_C$   $^{601}\text{Ser}$  to be phosphorylated to allow 14-

15 3-3 binding, we then examined whether  $^{601}\text{Ser}$  was phosphorylated *in vivo* and whether its phosphorylation was regulated by GM-CSF. These possibilities were initially addressed using  $^{32}\text{P}$ -orthophosphate labelled HEK 293T cells transfected with the GM-CSF receptor ( $\alpha$  and  $\beta_C$  subunits). These cells were stimulated with GM-CSF, total  $\beta_C$  was immunoprecipitated and examined for  $^{32}\text{P}$ -labelling. This is

20 most likely due to the presence of sixty serine and threonine residues in the intracellular region of  $\beta_C$ , some of which may be constitutively phosphorylated. In order to directly address the phosphorylation status of  $\beta_C$   $^{601}\text{Ser}$  *in vivo*, we raised a rabbit antiserum against a peptide containing the 14-3-3 binding site identified in  $\beta_C$ :  $^1\text{C}^{594}\text{LGPPHSRSLPDILG}^{607}$  (SEQ ID NO:39). This antibody

25 preparation, termed anti-phospho-  $^{601}\text{Ser}$  specifically recognised the CLGPPHSRSLPDILG (SEQ ID NO:39) peptide containing a phosphorylated  $^{601}\text{Ser}$  but not a peptide containing a non-phosphorylated  $^{601}\text{Ser}$  or a peptide containing a scrambled 14-3-3 binding site (Figure 10). The specificity of the anti-phospho-  $^{601}\text{Ser}$  antibody was further confirmed by Western blotting of

30 immunoprecipitated  $\beta_C$  from GM-CSF receptor-transfected HEK 293T cells. In these experiments, the phosphorylated CLPPHSRSLPDILG peptide (SEQ ID NO:39) was able to inhibit anti-phospho-  $^{601}\text{Ser}$  recognition of  $\beta_C$ , while the non-phosphorylated and scrambled peptides did not (Figure 10b). In addition,

#### Substitute Specification

pretreatment of  $\beta_C$  immunoprecipitates with calf intestinal phosphatase prior to Western blot analysis completely abolished the anti-phospho- <sup>601</sup>Ser signal and immunoprecipitation of either the wild type  $\beta_C$  or the <sup>598</sup>HSRSLP<sup>603</sup> (SEQ ID NO:31)→EFAAAA (SEQ ID NO:43) mutant from HEK293T transfected cells followed by western blot analysis with the anti-phospho- <sup>601</sup>Ser antibody demonstrated that this antibody specifically recognised the wild type but not the mutant receptor (data not shown).

Using these anti-phospho- <sup>601</sup>Ser specific antibodies we then examined the regulation of  $\beta_C$  <sup>601</sup>Ser phosphorylation following GM-CSF stimulation of M1 myeloid leukaemic cells. M1 myeloid leukaemic cells were stimulated with 2 ng/ml GM-CSF,  $\beta_C$  was immunoprecipitated, and immunoprecipitates probed with the anti-phospho- <sup>601</sup>Ser antibody. As shown in Figure 10, GM-CSF stimulation strongly upregulated <sup>601</sup>Ser phosphorylation of  $\beta_C$ .

## EXAMPLE 5

### IL-3 INDUCES Ser601 PHOSPHORYLATION OF $\beta_C$ AND RECRUITMENT OF 14-3-3.

We have described the biochemical interaction of the  $\beta_C$  of the GM-CSF, IL-3 and IL-5 receptors with the 14-3-3 family of phospho-serine binding proteins. These studies identified a motif, <sup>598</sup>HSRSLP<sup>603</sup> (SEQ ID NO:31), in the cytoplasmic domain of  $\beta_C$  that binds 14-3-3 when Ser601 is phosphorylated. To address the functional significance of 14-3-3 binding to  $\beta_C$  we generated cell lines expressing either wild type or mutant IL-3 receptors lacking the 14-3-3 binding site. CTL-EN cells were transduced with viral constructs expressing IL-3Ra and either wt $\beta_C$ , a substitution mutant that encompasses the 14-3-3 binding site ( $\beta_C$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43)) or a point mutant in which Ser601 of the 14-3-3 binding motif was substituted for alanine ( $\beta_C$ S601A). The  $\beta_C$ S601A point was not able to be used in these studies as it appeared to introduce a cryptic proteolytic cleavage site. Western blot analysis and flow cytometry indicated that this mutant was proteolysed and failed to be expressed on the cell surface (Stomski et al., 1999) Blood, 94, 1933-1942). Similar expression levels of wt $\beta_C$

and  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were observed in the CTL-EN cells by both flow cytometry (data not shown) and Western blot analysis (see below). Similar expression levels of IL-3Ra were also observed for each cell line.

5

The regulation of  $\beta_c$ Ser601 phosphorylation in response to IL-3 stimulation was then examined in these cell lines using anti-phospho-Ser601 $\beta_c$  antibodies. These antibodies have been shown to specifically recognize the phosphorylated 14-3-3 binding motif HSRSLP (where S is phosphorylated) but not the non-phosphorylated motif. CTL-EN cells expressing wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were starved for 4 hours in 0.1% FCS and then stimulated with 50ng/ml of IL-3. The  $\beta_c$  was immunoprecipitated and then subjected to immunoblot analysis using the anti-phospho- Ser601 $\beta_c$  antibodies. Ser601 phosphorylation was upregulated in response to IL-3 stimulation in CTL-EN cells expressing wt while no signal was detected for the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant control (Fig. 11a). Tyrosine phosphorylation of  $\beta_c$  was detected for both the wt $\beta_c$  and the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant (Fig. 11a). Co-immunoprecipitation experiments showed that increased  $\beta_c$ Ser601 phosphorylation in response to IL-3 stimulation also resulted in increased 14-3-3 binding to  $\beta_c$  (Fig. 11b). No association of 14-3-3 with the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant control in response to IL-3.

#### 25 **EXAMPLE 6** **cAMP-DEPENDENT PROTEIN KINASE (PKA) PHOSPHORYLATES Ser585 OF**

In an effort to identify the kinase involved in the phosphorylation of Ser601, we firstly examined the ability of several kinases to phosphorylate the purified recombinant intracellular portion of  $\beta_c$  (his $\beta_c$ 445-881) *in vitro*. Ser601 of  $\beta_c$  lies within a SXXD motif (SEQ ID NO:46) which is known to be a CKII consensus phosphorylation site. Ser601 also lies within a RS motif which is a possible, but poor, PKA phosphorylation site. In the *in vitro* kinase assay shown in Figure 12a, <sup>32</sup>P-labelling of his $\beta_c$ 445-881 was observed for both PKA and CKII. Additional bands for the PKA kinase reactions were evident due to the autocatalytic activity

30

of PKA. Interestingly, the presence of a non-phospho-HSRSLP peptide reduced the phosphorylation of his $\beta_c$ 445-881 by PKA whereas a phospho-HSRSLP or a scrambled peptide did not (Fig. 12a). In this experiment, the non-phospho-HSRSLP peptide is likely to act as a competitive substrate for phosphorylation of

5 Ser601 of his $\beta_c$ 445-881 by PKA. The phospho-HSRSLP and scrambled peptides would not act as competitive substrates and therefore did not result in decreased phosphorylation of his $\beta_c$ 445-881. On the other hand, the phosphorylation of his $\beta_c$ 445-881 by CKII was not inhibited by any of the peptides suggesting that CKII cannot phosphorylate Ser601 of his $\beta_c$ 445-881 (Fig. 12a).

10

To further examine the possibility that PKA could phosphorylate Ser601 of  $\beta_c$ , we performed *in vitro* kinase assays using cold ATP and examined the phosphorylation of Ser601 by immunoblot analysis using the anti-phospho-Ser601 $\beta_c$  antibodies. CKII was not able to detectably phosphorylate Ser601 of

15 his $\beta_c$ 445-881 whereas PKA resulted in strong phosphorylation of Ser601 as detected by the anti-phospho- Ser601 antibody (Fig. 12b). The results shown in Figure 12a and 12b support the proposal that PKA can phosphorylate Ser601 of  $\beta_c$  *in vitro*. We then examined the ability of PKA to phosphorylate Ser601 of  $\beta_c$  *in vivo*. CTL-EN cells expressing wt $\beta_c$  were starved for 12 hours in DMEM

20 containing 0.5% FCS and then either left unstimulated (nil), stimulated with 50ng/ml IL-3, 50mM forskolin or 100m dibutyryl cAMP for 10 minutes. Cells were lysed,  $\beta_c$  was immunoprecipitated and subjected to immunoblot analysis with the anti-phospho- Ser601 antibody. IL-3 stimulation resulted in increased Ser601 phosphorylation (Fig. 12c, IL-3). In addition, agents that elevate intracellular

25 levels of cAMP and activate PKA were also found to result in increased Ser601 phosphorylation of  $\beta_c$ . Together, the results shown in Figure 12 would suggest that PKA is likely to phosphorylate Ser601 of  $\beta_c$  in response to IL-3 stimulation.

## EXAMPLE 7

### 30 14-3-3 RECRUITMENT TO $\beta_c$ IN RESPONSE TO IL-3 IS IMPORTANT FOR THE ACTIVATION OF THE PI 3-KINASE PATHWAY.

The regulation of Ser601 phosphorylation and the recruitment of the phosphoserine adaptor protein 14-3-3 to  $\beta_c$  raised the possibility that these events were

**Substitute Specification**

important in regulating IL-3 signalling. GM-CSF and IL-3 are known to activate at least three pathways; the JAK/STAT pathway, the ras/MAP kinase pathway and the PI 3-kinase pathway (Guthridge et al., 1998 skin cells 16, 301-313). These pathways are not necessarily mutually exclusive and may have substantial overlap. The PI 3-kinase pathway has been implicated as having an important role in regulating cellular survival in a number of systems (Marte and Downward, (1997); Trends Biochem Sci 22, 355-358 cell, 88, 435-437) Franke et al., 1997) and, significantly, has been shown to bind 14-3-3 (Bonney-Berard et al., (1995); Lui et al., 1996). We therefore examined the possibility that Ser601 of  $\beta_c$  and 14-3-3 maybe important in the regulation of the PI 3-kinase pathway. CTL-EN cells expressing wt $\beta_c$ , or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were starved and stimulated with IL-3, tyrosine phosphorylated proteins were immunoprecipitated and the PI 3-kinase activity of the immunoprecipitates was determined in an *in vitro* kinase assay using phosphatidyl inositol and  $g^{32}P$ -ATP as substrates. While IL-3 stimulation of cells expressing wt $\beta_c$  resulted in the rapid and transient activation of PI 3-kinase activity, no PI 3-kinase activity was observed in response to IL-3 stimulation for the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant indicating that 14-3-3 binding to is necessary for PI 3-kinase activation (Fig. 13a).

20

Although  $\beta_c$  does not contain a classical YXXM consensus for the direct binding of PI 3-kinase, our results raise the possibility of an alternative mechanism whereby 14-3-3 could act as an adaptor to recruit PI 3-kinase to  $\beta_c$  via phospho-Ser601. To examine this possibility we performed co-immunoprecipitation experiments examining the association of  $\beta_c$  with the p85 regulatory subunit of PI 3-kinase. CTL-EN cells expressing wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were stimulated with IL-3 for up to 30 minutes,  $\beta_c$  was immunoprecipitated and the immunoprecipitates were examined for associated p85 subunit by immunoblot analysis. IL-3 stimulation resulted in the association of p85 with wt $\beta_c$  which was maximal at 5 minutes and was decreased by 30 minutes (Fig. 13b). In contrast, the recruitment of p85 to the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant in response to IL-3 was virtually abolished (Fig. 13b). We also examined the ability of the mutant  $\beta_c$  to

30

recruit the protein tyrosine phosphatase, SHP2. Previous studies have shown that Tyr612, which lies adjacent to the 14-3-3 binding site, is a likely binding site for SHP2 (Sakamaki K et al., 1992; Bone et al., 1997). Both the wt $\beta_c$  and the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant receptors were

5 able to recruit SHP2 in response to IL-3 indicating that the 14-3-3 binding mutant did not induce structural alterations that prevented the recruitment of other signalling molecules. These results suggest that 14-3-3 interaction with  $\beta_c$  is necessary for the recruitment of PI 3-kinase.

10 The interaction of  $\beta_c$  with PI 3-kinase was further addressed by examining the ability of the p85 subunit of PI 3-kinase to interact with purified his-tagged intracellular-portion of  $\beta_c$  (his $\beta_c$ 445-881) via the phosphorylated HSRSLP motif. his $\beta_c$ 445-881 expressed in bacteria is not phosphorylated on Ser601, however

15 as shown in Figure 12a and 12b, we have found that cAMP-dependent protein kinase (PKA) can efficiently phosphorylate Ser601 of his $\beta_c$ 445-881 *in vitro*. his $\beta_c$ 445-881 coupled to Sepharose and phosphorylated on Ser601 by PKA was incubated with COS-7 cell lysates and examined for its ability to pull-down p85 by immunoblot analysis. In addition, a number of peptides encompassing the 14-3-3

20 binding site in  $\beta_c$  (listed in Fig. 13c) were examined for their ability to competitively inhibit the interaction of his $\beta_c$ 445-881 with p85 (Fig. 12c). his $\beta_c$ 445-881 Sepharose was able to pull down p85 from the COS-7 cell extracts (Fig. 13d, lane 1) and the presence of scrambled (Fig. 13d, lane 2), Ser601Ala (Fig. 13d, lane 3), or non-phosphorylated- Ser601 (Fig. 13d, lane 4) control

25 peptides had no apparent effect on this interaction. On the other hand, the interaction of p85 with his $\beta_c$ 445-881 was markedly reduced in the presence of a phospho- Ser601 peptide (Fig. 13d, lane 5). Because the recombinant his $\beta_c$ 445-881 is not tyrosine phosphorylated and that only a phospho- Ser601 peptide could compete for p85 binding to  $\beta_c$ , these results suggest that Ser601 phosphorylation of  $\beta_c$  is responsible for the association of both 14-3-3 and p85.

30

To further examine if 14-3-3 binding to  $\beta_c$  was involved in regulating other signalling pathways besides the PI 3-kinase pathway, we investigated a number of additional signalling molecules known to be activated in response to IL-3. CTL-

EN cells expressing either wt $\beta_c$  or the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) receptors were starved and then stimulated with IL-3 and the activation of Akt (or protein kinase B), the signal transducer and activator of transcription protein STAT5, and the extracellular-regulated kinases ERK1 and ERK 2 (or MAP kinase) was examined in whole cell lysates by Western blot using phospho-specific antibodies. Akt is a known downstream target of PI 3-kinase whereas STAT5 and ERK are thought to be regulated by pathways distinct from the PI 3-kinase pathway. CTL-EN cells expressing wt $\beta_c$  or the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant induced STAT5 and ERK phosphorylation in response to IL-3 (Fig. 14a). While CTL-EN cells expressing wt $\beta_c$  demonstrated phosphorylation of Akt in response to IL-3, the phosphorylation of Akt was almost completely abolished in cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant (Fig. 14a). The activation of c-jun N-terminal kinase (JNK) was also examined in JNK immunoprecipitates using an *in vitro* kinase assay and GST-jun as a substrate. CTL-EN cells expressing either wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were able to induce JNK activity in response to IL-3 (Fig. 14b). Together, these results show that phosphorylation of Ser601 of  $\beta_c$  and 14-3-3 association are important for the recruitment of PI 3-kinase to  $\beta_c$  as well as the activation of its downstream signalling partner Akt. Furthermore, Ser601 phosphorylation of  $\beta_c$  and 14-3-3 binding are important for the specific regulation of the PI 3-kinase pathway but not for the regulation of other known pathways emanating from  $\beta_c$  that utilize STAT5, ERK or JNK.

25

## EXAMPLE 8

### ASSOCIATION OF 14-3-3 WITH $\beta_c$ IS IMPORTANT FOR IL-3-MEDIATED CELL SURVIVAL BUT NOT PROLIFERATION.

Given that 14-3-3 binding to Ser601 of  $\beta_c$  is required for PI 3-kinase activation in response to IL-3 and also the important role PI 3-kinase is thought to play in mediating survival signals, we then examined the ability of IL-3 to promote long-term survival in CTL-EN cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant receptor. Initial experiments performed

30

in the presence of 10% FCS showed no defect in either the survival or growth of CTL-EN cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant receptor (data not shown). However, a clear defect in the survival of CTL-EN cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:4) mutant was observed under low serum conditions. CTL-EN cells expressing the wt IL-3 receptor remain greater than 90% viable for up to 3-4 days under low serum conditions (0.1% FCS) in the presence of IL-3. To test the ability of IL-3 to promote cell survival, CTL-EN cells expressing either wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were plated out at  $2.5 \times 10^5$  cells/ml in the presence of IL-3 or IL-2 in medium containing 0.1% FCS and viable cells were counted after 4 days. While CTL-EN cells expressing wt $\beta_c$  remained greater than 90% viable for up to 3-4 days in the presence of either IL-3 or IL-2, cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant showed a loss of viability in the presence of IL-3 with only 7% viable cells remaining after 4 days (Fig 15a). Cells expressing the mutant receptor were able to maintain viability in the presence of IL-2. Importantly, CTL-EN cells expressing the wt $\beta_c$  lost viability in the presence of IL-3 and the PI 3-kinase inhibitor, LY294002, confirming that PI 3-kinase activity is essential for the survival these cells (Fig. 15a). As the defect in survival was apparent under low serum conditions (0.1% FCS) but not in the presence of 10% FCS, these results would suggest that there are factors in serum that can, at least in part, activate survival signals similar to those induced by IL-3. In fact, we have found that while serum is neither necessary for the promotion of CTL-EN cell survival (IL-3 in serum-free medium can promote survival of CTL-EN cells expressing the IL-3 receptor) nor sufficient in promoting survival (10% FCS fails to promote survival of CTL-EN cells expressing the IL-3 receptor) it can clearly augment the ability of IL-3 to stimulate cell survival (unpublished observations and these studies).

Loss of cell viability in CTL-EN cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) in response to IL-3 was also reflected in loss of cellular metabolic activity as determined by the MTS reduction assay. CTL-EN cells expressing wt $\beta_c$  maintain appreciable levels of metabolic activity in the presence of IL-3 and 0.1% FCS for up to 3 days but lost metabolic activity in the

absence of hIL-3 (Fig. 15b). CTL-EN cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant receptor lost metabolic activity in the presence of IL-3 (Fig. 15b). These data further suggest that the association of 14-3-3 with  $\beta_c$  in response to IL-3 is important for maintaining cellular viability.

5

To determine if the signalling defect of the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) receptor was specifically related to cell survival or if cell proliferation was also impaired, cell cycle progression in response to IL-3 was examined. CTL-EN cells were starved in medium containing 0.1% FCS and no IL-3 for 24 hours and then stimulated with IL-3 for up to 24 hours. The cells were then fixed in ethanol and the cell cycle distribution was examined by prodidium iodide staining and flow cytometry. Under these starvation conditions, nearly 90% of CTL-EN cells accumulate in the  $G_0/G_1$  phase of the cell cycle (Fig. 16a). CTL-EN cells expressing either wt $\beta_c$  or the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant and synchronized in  $G_0/G_1$  were both able to re-enter the cell cycle in response to IL-3 indicating that Ser601 phosphorylation, and 14-3-3 binding are not essential for signals that promote cell cycle progression (Fig. 16a). We also examined the regulation of c-myc mRNA expression in response to IL-3 by Northern blot analysis. The induction of c-myc is proposed to be an important pre-requisite for cell proliferation. No impairment of c-myc mRNA induction was observed in CTL-EN cells expressing  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) when compared to control cells expressing wt $\beta_c$  (Fig. 16b).

#### EXAMPLE 9

##### 25 LOSS OF 14-3-3 BINDING TO $\beta_c$ RESULTS IN CELL DEATH BY APOPTOSIS.

We then performed Annexin V binding studies to determine if the loss in cell viability in CTL-EN cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant was due to apoptosis. CTL-EN cells expressing wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were washed and placed in medium containing 0.1% FCS and either IL-2 or IL-3 for 16 hours. The cells were then stained with annexin V and apoptotic cells were analysed by flow cytometry. CTL-EN cells expressing wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID

NO:4)→EFAAAA (SEQ ID NO:43) showed negligible annexin V staining in the presence of IL-2 (Fig. 17). However, in the presence of IL-3, CTL-EN cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant showed increased annexin V staining compared to cells expressing the wt $\beta_c$  indicating that the defect in cell survival is due to increased apoptosis (Fig. 17).

#### EXAMPLE 10

##### IL-3 INDUCES Ser601 PHOSPHORYLATION OF $\beta_c$ AND RECRUITMENT OF 14-3-3.

To address the functional significance of 14-3-3 binding to  $\beta_c$  cell lines were generated expressing either wild type (wt) or mutant IL-3 receptors lacking the 14-3-3 binding site. Constructs expressing the IL-3-specific  $\alpha$  chain (IL-3R $\alpha$ ), and either wt  $\beta_c$ ,  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43),  $\beta_c$ RSL (SEQ ID NO:44)→AAA (SEQ ID NO:45),  $\beta_c$ S601A or  $\beta_c$ S601G were introduced into the CTL-EN T-cell line.

The regulation of  $\beta_c$ Ser601 phosphorylation in response to IL-3 stimulation was examined in these cell lines using the anti-phospho- Ser601 $\beta_c$  antibody. These antibodies have been shown to specifically recognize the phosphorylated 14-3-3 binding motif HSRSLP (where S is phosphorylated) but not the non-phosphorylated motif (Stomski et al., 1999). CTL-EN cells expressing IL-3R $\alpha$  and either wt $\beta_c$ ,  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) or  $\beta_c$ Ser601 were factor-deprived for 12 hours in 0.5% FCS and then stimulated with 50ng/ml of IL-3. The  $\beta_c$  was immunoprecipitated and then subjected to immunoblot analysis using the anti-phospho-Ser601 $\beta_c$  antibody. Ser601 phosphorylation was upregulated in response to IL-3 stimulation in CTL-EN cells expressing wt $\beta_c$  while no signal was detected for either the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) or the  $\beta_c$ S601G mutant controls (Fig. 20A). Co-immunoprecipitation experiments showed that increased  $\beta_c$ Ser601 phosphorylation in response to IL-3 stimulation also resulted in increased 14-3-3 binding to  $\beta_c$  (Fig. 20A). No association of 14-3-3 with the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) or the  $\beta_c$ S601G mutant controls in response to IL-3 was observed. In addition, the MO7e cell line which expresses endogenous IL-3 receptors also

demonstrated increased Ser601 phosphorylation and 14-3-3 recruitment in response to IL-3 stimulation (Figure 20B). No difference in the kinetics or extent of tyrosine phosphorylation was observed for the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43),  $\beta_c$ RSL (SEQ ID NO:44)→AAA (SEQ ID NO:45) or the  $\beta_c$ S601G mutants when compared to the wt $\beta_c$  receptor (Fig. 20C). The stoichiometry of Ser601 phosphorylation in response to IL-3 *in vivo* was also examined and compared to  $\beta_c$  tyrosine phosphorylation. In these experiments,  $\beta_c$  was immunoprecipitated from I<sup>125</sup> surface-labelled CTL-EN cells (to avoid detection of intracellular-only  $\beta_c$ ) with either anti-phosphor Ser601, anti-phosphotyrosine or anti- $\beta_c$  antibodies from both IL-3-stimulated (+IL-3) or non-stimulated (-IL-3) cells expressing wt $\beta_c$  or  $\beta_c$ S601G receptors. Immunoprecipitates were electrophoresed on a polyacrylamide gel and the amount of radiolabelled receptor immunoprecipitated was quantified using a phosphorImager. In non-stimulated cells (wt $\beta_c$ ,  $\beta_c$  as the receptor is not phosphorylated on either Ser601 or tyrosine (Fig. 20D). Following IL-3 stimulation, similar amounts of wt $\beta_c$  were immunoprecipitated with the anti-phospho Ser601 $\beta_c$  and anti-phosphotyrosine antibodies when compared to the anti- $\beta_c$  antibodies. Quantification of the bands indicated that in cells expressing the wt $\beta_c$ , approximately 87% of surface-labelled  $\beta_c$  is phosphorylated on Ser601 and approximately 94% of  $\beta_c$  is phosphorylated on tyrosine. While the anti-phospho Ser601 $\beta_c$  antibodies did not immunoprecipitate  $\beta_c$ S601G from IL-3 stimulated cells, both anti-phosphotyrosine and anti- $\beta_c$  antibodies did. Approximately 95% of the surface-labelled  $\beta_c$ S601G was tyrosine phosphorylated following IL-3 stimulation which was comparable to the amount of wt $\beta_c$  tyrosine phosphorylation. As we have previously reported (Stomski et al., 1996), immunoprecipitation of the  $\beta_c$  from I<sup>125</sup> surface-labelled cells following IL-3 stimulation results in the co-immunoprecipitation of IL-3R $\alpha$ . Similar levels of IL-3R $\alpha$  were co-immunoprecipitated with the anti $\beta_c$  antibodies from cells expressing either wt $\beta_c$  or  $\beta_c$ S601G indicating that the receptor mutant is not impaired in its ability to dimerize with IL-3R $\alpha$  in response to ligand (Fig. 20D).

## EXAMPLE 11

**cAMP-DEPENDENT PROTEIN KINASE (PKA) PHOSPHORYLATES Ser585 of** **$\beta_c$** 

In an effort to identify the kinase involved in the phosphorylation of Ser601, the ability of several kinases to phosphorylate the recombinant intracellular portion (amino acids 445-881) of  $\beta_c$  (His $\beta_c$ 445-881) *in vitro* was examined. Ser601 of  $\beta_c$  lies within an <sup>585</sup>SXXD<sup>588</sup> (SEQ ID NO:46) motif which is a possible casein kinase II (CKII) consensus phosphorylation site and also within an <sup>582</sup>HSRS<sup>585</sup> (SEQ ID NO:47) motif which is a possible, but poor, cAMP-dependent protein kinase (PKA) consensus phosphorylation site (Kennely and Krebs, (1991)) (J. Biol. Chem. 266, 15,555-15,558). In the *in vitro* kinase assay shown in Figure 21A, <sup>32</sup>P-labelling of purified His $\beta_c$ 445-881 was observed for both PKA and CKII. Additional bands for the PKA kinase reactions were evident due to the autocatalytic activity of PKA. Interestingly, the presence of a non-phospho-Ser601 peptide reduced the phosphorylation of His $\beta_c$ 445-881 by PKA (presumably acting as a competitive substrate) whereas a phospho- Ser601 or a scrambled peptide did not (Fig. 21A). Furthermore, while CKII can clearly phosphorylate His $\beta_c$ 445-881, the phosphorylation was not inhibited by any of the peptides suggesting that CKII does not phosphorylate Ser601 (Fig. 21A).

20

The ability of PKA or CKII to specifically phosphorylate Ser601 of His $\beta_c$ 445-881 was then examined by immunoblot analysis using the anti-phospho-Ser601 $\beta_c$  antibody. CKII was not able to detectably phosphorylate Ser601 of His $\beta_c$ 445-881 whereas PKA caused strong phosphorylation of Ser601 as detected by the anti-phospho- Ser601 antibody (Fig. 21B). We then examined the affinity of PKA for the non-phospho-Ser601 peptide and the kinetics of phosphorylation. The apparent  $K_m$  and  $V_{max}$  for this peptide derived from hyperbolic regression analysis was 376 $\mu$ M and 250 nmol/min/mg respectively (Fig. 21C).

As the results shown in Figure 21A-C suggested that PKA could phosphorylate Ser601 of  $\beta_c$  *in vitro* with  $K_m$  and  $V_{max}$  values within the physiological range of other known PKA substrates, we then examined the ability of PKA to phosphorylate Ser601 of  $\beta_c$  *in vivo* was examined. CTL-EN cells expressing the

**Substitute Specification**

wt $\beta_c$  were factor-deprived for 12 hours and then either not stimulated (nil), or stimulated with 50 ng/ml IL-3, 50  $\mu$ M forskolin or 100  $\mu$ M dibutyryl cAMP (db-cAMP) for 10 minutes. In addition, the ability of the PKA inhibitor, H89, to block IL-3-induced phosphorylation of Ser601 of  $\beta_c$  was examined. For these experiments, either CTL-EN cells expressing the wt $\beta_c$  or MO7e cells were either not stimulated (nil), stimulated for 10 minutes with IL-3 (IL-3), or pretreated with 30 $\mu$ M H89 for 15 minutes prior to IL-3 stimulation for 10 minutes (H89 + IL-3). After various treatments, cells were lysed,  $\beta_c$  was immunoprecipitated, and subjected to immunoblot analysis with the anti-phospho- Ser601 antibody. IL-3 stimulation, as well as stimulation with agents that activate PKA (forskolin and db-cAMP), resulted in increased Ser601 phosphorylation (Fig. 21D). Furthermore, blocking PKA activation with H89 significantly reduced the IL-3 induced phosphorylation of Ser601 in both CTL-EN cells and MO7e cells.

## EXAMPLE 12

### **14-3-3 RECRUITMENT TO $\beta_c$ IN RESPONSE TO IL-3 COUPLES THE IL-3 RECEPTOR TO THE PI 3-KINASE PATHWAY.**

The regulation of Ser601 phosphorylation and the recruitment of 14-3-3 to  $\beta_c$  raised the possibility that these events were important in regulating IL-3 signalling. GM-CSF and IL-3 are known to regulate at least three, not necessarily mutually exclusive pathways; the JAK/STAT, the ras/MAP kinase and the PI 3-kinase pathways. The possibility that Ser601 of  $\beta_c$  and 14-3-3 association may be important in the regulation of the PI 3-kinase pathway in response to IL-3 was examined. CTL-EN cells expressing IL-3R $\alpha$  and either the wt $\beta_c$ , the  $\beta_c$ HSRSLP (SEQ ID NO:4) $\rightarrow$ EFAAAA (SEQ ID NO:43) mutant or the  $\beta_c$ S585G mutant were factor-deprived, stimulated with IL-3, tyrosine phosphorylated proteins were immunoprecipitated, and the PI 3-kinase activity of the immunoprecipitates was determined in an *in vitro* kinase assay using phosphatidylinositol and  $\gamma^{32}$ P-ATP as substrates. IL-3 stimulation of cells expressing wt $\beta_c$  resulted in the rapid and transient activation of PI 3-kinase activity which was blocked by the PI 3-kinase inhibitors Wortmannin and LY294002 (Fig. 22A). No PI 3-kinase activity was observed in response to IL-3 stimulation for either the  $\beta_c$ HSRSLP (SEQ ID

NO:4)→EFAAAA (SEQ ID NO:43) or the  $\beta_c$ S601G mutants suggesting that 14-3-3 binding is necessary for PI 3-kinase activation (Fig. 22A). As positive controls, p85 immunoprecipitates prepared from non-starved CTL-EN cells expressing either wt $\beta_c$ ,  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) or  $\beta_c$ S601G were examined and PI 3-kinase activity was clearly detectable for both cell lines.

As  $\beta_c$  does not contain a classical YXXM consensus for the direct binding of PI 3-kinase, our results raised the possibility that 14-3-3 could act as an adaptor to recruit PI 3-kinase to  $\beta_c$  via phospho-Ser601. To address this possibility we performed co-immunoprecipitation experiments examining the association of  $\beta_c$  with the p85 regulatory subunit of PI 3-kinase. CTL-EN cells expressing IL-3R $\alpha$  and either wt $\beta_c$ ,  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) or  $\beta_c$ S601G were stimulated with IL-3,  $\beta_c$  was immunoprecipitated and the immunoprecipitates were examined for associated p85 subunit by immunoblot analysis. IL-3 stimulation resulted in the recruitment of p85 to wt $\beta_c$  whereas no recruitment of p85 to the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) or the  $\beta_c$ S601G mutants was observed (Fig. 22B).

To further examine the possibility that 14-3-3 could couple  $\beta_c$  to PI 3-kinase, we performed pull-down experiments using recombinant intracellular-portion of  $\beta_c$  (His $\beta_c$ 445-881). The results presented above indicated that the association of 14-3-3 with the <sup>598</sup>HSRSLP<sup>603</sup> motif (SEQ ID NO:31) of  $\beta_c$  and the subsequent recruitment of PI 3-kinase is dependent on the phosphorylation of Ser601. We have also shown that PKA can efficiently phosphorylate Ser585 of His $\beta_c$ 445-881 *in vitro* (Fig. 21A, B and C). We therefore examined the ability of His $\beta_c$ 445-881 coupled to Sepharose and phosphorylated on Ser601 by PKA to precipitate both p85 and 14-3-3 from COS-7 cell lysates. No interaction of either 14-3-3 or p85 was observed with Sepharose alone (Fig. 22C, lane 1) or unphosphorylated His $\beta_c$ 445-881 (lane 2), however, both 14-3-3 and p85 were precipitated from COS-7 cell lysates using PKA-phosphorylated His $\beta_c$ 445-881 (lane 3). A number of peptides encompassing the 14-3-3 binding site in  $\beta_c$  were examined for their ability to competitively inhibit the interaction of His $\beta_c$ 445-881 with p85 and 14-3-3.

His $\beta_c$ 445-881 Sepharose was able to pull-down p85 and 14-3-3 in the presence of the Ser601Ala (Fig. 22C, lane 4) or non-phospho-Ser601 (lane 5) control peptides, but this interaction was markedly reduced in the presence of a phospho-Ser601 peptide (lane 6). These results further indicate that the  
 5 recruitment of PI 3-kinase to  $\beta_c$  requires the presence of the HSRSLP (SEQ ID NO:4) 14-3-3-binding site in  $\beta_c$ .

To examine whether the recruitment of 14-3-3 to  $\beta_c$  was specifically involved in signalling through the PI 3-kinase pathway, we investigated a number of  
 10 additional signalling molecules known to be activated in response to IL-3. CTL-EN cells expressing either wt $\beta_c$  or the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) receptors were factor-deprived and then stimulated with IL-3. The phosphorylation of the signal transducer and activator of transcription protein STAT5, and the extracellular-regulated kinases ERK1 and ERK 2 in response to  
 15 IL-3 was unaffected in cells expressing the mutant receptor when compared to cells expressing the wt $\beta_c$  (Fig. 23A). However, while CTL-EN cells expressing wt $\beta_c$  demonstrated phosphorylation of Akt in response to IL-3, the phosphorylation of Akt was almost completely abolished in cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant (Fig. 23A). The  
 20 activation of c-jun N-terminal kinase (JNK) was also examined in JNK immunoprecipitates using an *in vitro* kinase assay and GST-jun as a substrate. CTL-EN cells expressing either wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were both able to induce JNK kinase activity in response to IL-3 (Fig. 23B). Similarly, no differences in the tyrosine phosphorylation of the non-  
 25 receptor tyrosine kinase, JAK2 were observed (Fig. 23C). These results show that phosphorylation of Ser601 of  $\beta_c$  and 14-3-3 association are not only important for the recruitment and activation of PI 3-kinase, but also for the activation of its downstream signalling partner Akt. Furthermore, Ser601 phosphorylation of  $\beta_c$  and 14-3-3 binding are important for the specific regulation  
 30 of the PI 3-kinase pathway but not for the regulation of other known pathways emanating from  $\beta_c$  that utilize STAT5, ERK, JNK or JAK2.

**EXAMPLE 13****ASSOCIATION OF 14-3-3 WITH  $\beta_c$  IS REQUIRED FOR IL-3-MEDIATED CELL SURVIVAL BUT NOT PROLIFERATION.**

The finding that 14-3-3 binding to Ser601 of  $\beta_c$  is required for PI 3-kinase recruitment and activation in response to IL-3 and also the important role PI 3-kinase is thought to play in mediating survival signals raised the possibility that phosphorylation of Ser601 of  $\beta_c$  was important in regulating cell survival. Initial experiments performed in the presence of 10% FCS showed no defect in either the survival or growth of CTL-EN cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant receptor (data not shown). However, a defect in the survival of CTL-EN cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant was observed under low serum conditions. Thus, while serum is neither necessary nor sufficient in promoting IL-3-mediated CTL-EN cell survival (unpublished observations) it can augment IL-3-mediated survival in cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant receptor. CTL-EN cells expressing either wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were plated out at  $5 \times 10^5$  cells/ml in the presence of 10 ng/ml IL-3/0.1% FCS and viable cells were counted over 3 days. While IL-3 was able to promote viability of CTL-EN cells expressing wt $\beta_c$  for up to 3 days, cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant showed a loss of viability in the presence of IL-3 with only 18% viable cells remaining after 3 days (Fig 24A). The viability of CTL-EN cells expressing wt $\beta_c$  or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) were maintained in the presence of the IL-2 control cytokine.

25

Loss of cell viability in CTL-EN cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) in response to IL-3 was also reflected in loss of cellular metabolic activity as determined by the MTS reduction assay. CTL-EN cells expressing wt $\beta_c$  maintain appreciable levels of metabolic activity in the presence of 10ng/ml IL-3 (■) and 0.1% FCS for up to 3 days but lost metabolic activity in the absence of IL-3 (▼)(Fig. 24B). However, CTL-EN cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant receptor lost

30

metabolic activity in the presence of 10ng/ml IL-3 (Fig. 24B, ▲). To determine if the loss in cellular viability was due to apoptosis, we performed DNA laddering analysis. CTL-EN cells expressing either the wt $\beta_c$  or the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant were plated out as described above in

5 20 ng/ml IL-2, no factor (NF) or 50 ng/ml IL-3. Cells were harvested 48 hours later, the DNA extracted and subjected to agarose gel electrophoresis and ethidium bromide staining. DNA from CTL-EN cells expressing either wt $\beta_c$  or the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant exhibited the characteristic laddering typical of apoptotic cells in the absence of factor (NF)

10 while no significant DNA laddering was observed in the presence of IL-2 (Fig. 24C). CTL-EN cells expressing wt $\beta_c$  and plated in IL-3 showed no significant DNA laddering, however, DNA from CTL-EN cells expressing the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant which were plated in IL-3 showed a clear DNA ladder typical of apoptotic cells. As an additional means of examining

15 the mode of cell death we performed combined annexin V and propidium iodide staining. For these experiments we examined CTL-EN cells expressing the wt $\beta_c$ , and the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant as well as two additional mutants,  $\beta_c$ S601G and  $\beta_c$ RSL (SEQ ID NO:44)→AAA (SEQ ID NO:45). Cells were plated out in 20 ng/ml IL-2, no factor or 50 ng/ml IL-3, stained

20 with annexin V and propidium iodide after 30 hours and analysed by flow cytometry. In the presence of IL-2, low levels of apoptotic cells (annexin V and propidium iodide positive cells) were observed for CTL-EN cells expressing wt $\beta_c$  (11.8%)  $\beta_c$ S601G (15.3%),  $\beta_c$ RSL (SEQ ID NO:44)→AAA (SEQ ID NO:45) (8.9%), or  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) (10.0%)(Fig.

25 24D). In the absence of factor, increased apoptotic cells were detected for wt $\beta_c$  (50.0%),  $\beta_c$ S601G (45.1%),  $\beta_c$ RSL→AAA (55.0%), and the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) (37.0%) mutant. While IL-3 was able to protect CTL-EN cells expressing wt $\beta_c$  against apoptosis (24.1%), cells expressing the  $\beta_c$ S601G (46.5%),  $\beta_c$ RSL (SEQ ID NO:44)→AAA (SEQ ID NO:44) (51.2%),

30 and the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) (42.7%) mutants exhibited levels of apoptosis comparable to those observed in the absence of

factor (Fig. 24D). Together, the results shown in Figure 24C and 24D indicate that the defect in cell survival is due to increased apoptosis.

To determine if the signalling defect of the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) receptor was specifically related to cell survival or if cell proliferation was also impaired, cell cycle progression in response to IL-3 was examined. The cell cycle distribution of CTL-EN cells expressing the wt $\beta_c$  or the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant was examined in fixed and permeabilized cells by propidium iodide staining and flow cytometry. CTL-EN cells growing asynchronously in the presence of IL-2 have approximately 37% of cells in G<sub>0</sub>/G<sub>1</sub> phase of the cell cycle (Fig. 25A, asynchronous). Nearly 90% of CTL-EN cells accumulate in G<sub>0</sub>/G<sub>1</sub> following starvation for 24 hours in DMEM containing 0.1% FCS and no cytokine (Fig. 25A, starved). IL-3 stimulation of starved cells for 24 hours resulted in equivalent numbers of CTL-EN cells expressing either wt $\beta_c$  or the  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) mutant re-entering S phase and G<sub>2</sub>/M phase of the cell cycle (Fig. 25A, wt $\beta_c$  – 35.3%;  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) – 35.7%). These results indicate that Ser601 phosphorylation of  $\beta_c$  and 14-3-3 binding are not essential for promoting cell cycle progression. We also examined the regulation of c-myc mRNA expression in response to IL-3 by Northern blot analysis. The induction of c-myc is proposed to be an important pre-requisite for cell proliferation (Desbarats et al., 1996). No impairment of c-myc mRNA induction was observed in CTL-EN cells expressing  $\beta_c$ HSRSLP (SEQ ID NO:4)→EFAAAA (SEQ ID NO:43) when compared to control cells expressing wt $\beta_c$  (Fig. 25B).

30

#### EXAMPLE 14

#### Ser585 PHOSPHORYLATION AND PI 3-K SIGNALLING IS CONSTITUTIVE IN PRIMARY HUMAN AML CELLS.

AML cells were starved for 12h and then stimulated with GM-CSF for 5 minutes. Where indicated cells were pre-incubated in the PKA inhibitor, H89 (10 $\mu$ M), for 60 min. prior to GM-CSF stimulation. Cells were then lysed. (A) 75% of the lysates were subjected to  $\beta_c$  immuno-precipitation. Immunoprecipitates were subjected  
5 to SDS-PAGE, transferred to nitrocellulose and immunoblotted with anti-phospho-Ser601 $\beta_c$ . The filters were then stripped and reprobed with anti-phospho-tyrosine, anti-14-3-3, anti-p85 and anti- $\beta_c$ . (B) 25% of the lysates were subjected to anti-phosphotyrosine immuno-precipitation and PI 3-K assays were performed.

- 10 Finally it is to be understood that various other modifications and/or alterations may be made without departing from the spirit of the present invention as outlined herein.
